After the 1905 revolution some political activity developed and the Musavat (Equality) party was formed in 1911. The March 1917 revolution and the presence of the Turkish army in Transcaucasia brought about an alliance between the Musavat and Turkey. At the same time an attempt was made to found an independent Transcaucasian federation consisting of Azerbaijan, Georgia and Armenia. Racial and religious animosity caused this to fail and an independent republic of Azerbaijan was formed in May 1918, its capital being at Gandzha until Baku, which had been under the control of a Communist council, was captured with the help of the Turkish army in 1918. A small British force which had originally occupied Baku in Aug. 1918, but withdrew on the arrival of the Turks, returned after the collapse of Turkey in November and was virtually in control of the republic's affairs until it was finally evacuated in Aug. 1919. The new republic was recognized *de facto* by the Allied powers on Jan. 15, 1920. In April 1920 Azerbaijan was invaded by the Red army and the government surrendered to the Communist authorities. The Azerbaijan S.S.R. was created in the same month. In 1922 it was incorporated in the Transcaucasian Soviet Federated Socialist Republic until 1936 when it became a union republic.

Under the Soviet regime the economy of the republic was greatly developed. Of its political stability it is difficult to speak with

precision. In 1951 M. D. Bagirov, the first secretary of the Communist party of Azerbaijan, spoke of the existence of "political deviations" and "secret anti-government activities by enemies of the people." He was executed in April 1956.

AZHARI, ISMAIL AL- (1900–), Sudanese statesman, prime minister of Sudan from 1954 to 1956, was born at Omdurman on Oct. 30, 1900, of a family originally from Kordofan, a grandson of Sheikh Ismail al-Azhari, a former mufti of the Sudan. After an education in Sudanese schools he graduated at the American University of Beirut and from 1921 to 1946 served in the Sudanese department of education. Soon after the signature of the Anglo-Egyptian treaty of 1936, the disappointment of many articulate Sudanese at their exclusion from a voice in determining the future status of their country found expression in political organization, and al-Azhari, who in 1939 had been appointed first secretary to the Graduates' General congress, became its president in 1940.

Al-Azhari was later president of the Ashigga party, a body favourable to unity with Egypt, and in 1952 was made president of the broader-based National Unionist party. In Nov. 1953 he was elected to the house of representatives and in Jan. 1954 was chosen prime minister, thus becoming leader of the first all-Sudanese cabinet. His term of office was marked by the end of the Anglo-Egyptian condominium on Jan. 1, 1956, and the assumption of Sudanese sovereignty.

A realignment of political forces, the withdrawal of the support of the Khatmiyya religious brotherhood and the resignation of three ministers, however, precipitated the fall of al-Azhari's ministry in July 1956, when he was succeeded as prime minister by Abdullah Khalil. (R. L. Hl.)

AZO (Azzo, latinized as Azolinus Porcius) (*c.* 1150–1230), Italian jurist, was born at Bologna, studied under Johannes Bassianus and became professor of civil law at Bologna. Azo is occasionally described as Azo Soldanus or as Azzo Porcius. He is to be distinguished from the 13th-century canonist, Azo Lambertaccius, and the 14th-century canonist, Azo de Ramenghis. Azo occupied a very important position among the glossators. His *Summa codicis* and *Summa institutionum*, completed by the additions of Hugolinus Presbyteri and Odofredus, formed a methodical exposition of Roman law and were of such weight before the tribunals that it used to be said, "*Chi non ha Azzo, non vada al Palazzo*" ("He who has not learnt Azzo does not go to the palace [of justice]," *i.e.*, does not become a judge). Azo numbered among his pupils Franciscus Accursius and Jacobus Balduinus.

The extent to which Azo plagiarized the works of his predecessors, Placentinus and Bassanius, is disputed. Azo's work was more complete and had a more enduring reputation. In England, most of the Roman material used by Henry de Bracton (*q.v.*) in his *De legibus et consuetudinibus Angliæ* was derived from the *Summae* of Azo. (Rl. P.)

AZO COMPOUND. "Azo" is an abbreviated form of *azote*, an early name coined by Antoine Lavoisier for nitrogen. Azo compounds as outlined in this article are the organic chemical compounds which contain the group —N:N— attached to two hydrocarbon radicals and have the general formula RN:NR′, where R and R′ can be either an alkyl or a substituted or unsubstituted aryl group. Among the most important members of the family are the azo dyestuffs, which form an enormous class of chemical compounds; literally thousands of them have been made, and at least a thousand, each with a peculiar and valuable property, have come into world commerce. (*See* Dyes and Dyeing.)

Azo compounds are distinguished from the diazo compounds (*q.v.*), which also contain doubly linked nitrogen, in that each of the nitrogen atoms contained in the —N:N— grouping is bound to a carbon atom in the alkyl or aryl radical. For the most part, also, the azo compounds are much more stable and unreactive than the diazo compounds.

Nomenclature and Classification.—The simpler members of the azo class of compounds are readily named. Where R and R′ are unsubstituted and alike, the name used is that of the compound from which the radicals are derived with the prefix "azo"; thus CH_3—N:N—CH_3 is called azomethane, and C_6H_5—N:N—C_6H_5 azobenzene. If R and R′ are different the term "azo" is placed between the names of the compounds from which they are derived; thus C_6H_5—N:N—CH_3 is called benzeneazomethane. When R and R′ are both substituted aryl residues, and when the —N:N— group occurs more than once in the molecule, the naming of the compounds becomes very complicated, and systematic chemical nomenclature gives way to the use of trademarks, especially for the numerous members of this class which are used as dyestuffs.

From this consideration of the nomenclature of these compounds, it becomes apparent at once that they can be divided into three classes: (1) the aliphatic azo compounds where both R and R′ are alkyl residues; (2) the mixed aliphatic-aromatic azo compounds where R is an alkyl and R′ is an aryl residue; and (3) the aromatic azo compounds where both R and R′ are aryl residues. The third class is by far the most numerous and important of the azo compounds.

Aliphatic Azo Compounds.—Of the aliphatic azo compounds, azomethane, prepared by oxidizing *sym*-dimethylhydrazine hydrochloride with chromic acid, is best known. A gas at ordinary temperatures, it is readily condensed to a yellow liquid having a boiling point of 1.5° C. In no way does it behave as a base. At 200° C. it is thermally decomposed by a unimolecular reaction into nitrogen and free methyl radicals, the latter being detected in the usual manner by the use of metal mirrors. However, the free methyl radicals combine at once to form ethane, so that the whole equation may be written thus:

$$CH_3\text{—N:N—}CH_3 \rightarrow 2CH_3\cdot + N_2 \rightarrow CH_3.CH_3 + N_2$$

From a consideration of the first part of this reaction it would appear that azomethane should be an excellent methylating agent. Such is found to be the case. The other aliphatic azo compounds are prepared in a similar manner and react the same as azomethane. Chemically, they are of little importance.

Mixed Aliphatic-Aromatic Azo Compounds.—Of little importance, too, are the mixed aliphatic-aromatic azo compounds, of which benzeneazomethane and benzeneazoethane are best known. They are yellow liquids and can be prepared by oxidizing the corresponding hydrazo compounds in ether solutions by means of mercuric oxide. The first boils at 150° C., the second at 175°–185° C., with some decomposition. Both are readily steam distilled. The most interesting reaction of these products is that they are readily converted isomerically into hydrazones by the action of either 60% sulfuric acid or alcoholic sodium ethylate, as follows:

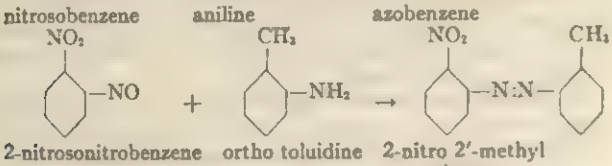
$$\underset{\text{benzeneazoethane}}{C_6H_5N\text{:N—}C_2H_5} \rightarrow \underset{\text{acetaldehyde phenylhydrazone}}{C_6H_5.NH.N\text{:}CH.CH_3}$$

Aromatic Azo Compounds.—The parent substance of the aromatic azo compounds is azobenzene, $C_6H_5.N\text{:}N.C_6H_5$, discovered in 1834 by Eilhardt Mitscherlich. It forms orange-red crystals melting at 66°–68° C. (*see* melting point of isomers below), and it boils without decomposition at 295° C. As in the case of many of its closely related compounds, it can be prepared by a wide variety of methods based primarily on four reactions. Thus azobenzene itself can be made (1) by the reduction of nitrobenzene, (2) by the reduction of azoxybenzene, (3) by the mild oxidation of hydrazobenzene, and (4) by the reaction of nitrosobenzene and aniline. The latter reaction, giving rather good yields,

and most useful in preparing substituted aromatic azo compounds, definitely establishes the chemical constitution of azobenzene and of its substituted products.

$$C_6H_5NO + C_6H_5NH_2 \rightarrow C_6H_5-N:N-C_6H_5+H_2O$$

nitrosobenzene aniline azobenzene



2-nitrosonitrobenzene ortho toluidine 2-nitro 2′-methyl azobenzene

A fifth method for making aromatic azo compounds, but not applicable in the case of azobenzene, is by "coupling" an aromatic diazo compound to a phenol or an aromatic amine. The coupling reaction is very difficult, if not entirely impossible, when a hydroxy or an amino group is not present in the aromatic molecule to which the diazo compound is to be coupled.

Oxidation of the aromatic azo compounds with mild oxidizing agents gives the azoxy compounds, while reduction gives first the hydrazo compounds and then the primary amines.

$$2Ar.N:N.Ar+O_2 \rightarrow 2Ar.\underset{\underset{O}{|}}{N}:N.Ar$$

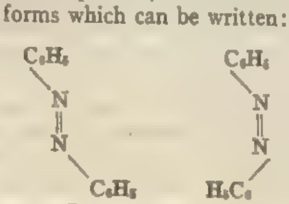
$$Ar.N:N.Ar+2H_2 \rightarrow Ar.NH.NH.Ar \rightarrow 2ArNH_2$$

The reduction reaction is of great technical importance, for by the use of reducing agents such as stannous or titanous salts, or sodium hydrosulfite, $Na_2S_2O_4$, the azo dyestuffs, which may contain from one to four —N:N— groupings, are broken down into primary amines, thus giving the structure of the dyes under examination. Moreover, this reaction is so exact that it is useful in the quantitative determination of the azo grouping.

Azo dyestuffs are primarily hydroxy- and amino-substituted aromatic azo compounds, and by far the greater number also contain one or more sulfonic acid groups. Almost invariably they are made by coupling aromatic diazo compounds with phenols and aromatic amines.

With the addition of the hydroxy and amino groups the colour of the azo compounds is much deeper than with azobenzene itself, and as the molecules become more complex, with more than one azo group present and with each aromatic residue containing additional OH or NH_2 groups, the absorption of light moves toward the red end of the spectrum, so that dyestuffs of every shade of colour, from light yellow to deep black, can be obtained.

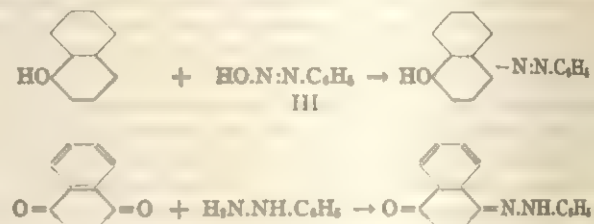
Azobenzene itself is of considerable theoretical interest. Because of the space arrangement of the groups attached to the doubly bound nitrogen atoms there is the possibility of stereoisomerism in these compounds, and thus azobenzene should exist in two isomeric forms which can be written:



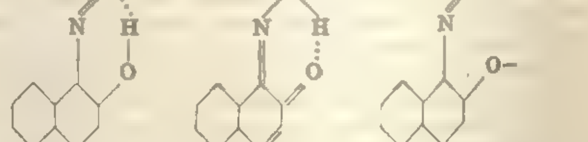
I II

Azobenzene, melting at 68° C., and made by the reduction of nitrobenzene or azoxybenzene is the *trans*-compound (I), as shown by X-ray crystallographic examination. In 1937, G. S. Hartley published the results of work which indicated that when solutions of this material were exposed to sunlight, parts of the *trans*-compound were converted to the *cis*-form (II). Studying the rate and extent of conversion in various solvents, he and his coworkers found that as much as 40% of the *cis*-isomer could be obtained in certain solvents such as acetone. He also determined that the two isomers could be separated from each other by their different solubilities in water and other solvents or by chromatographic means. He also established the fact that *cis*-azobenzene melts at 71.4° C., being converted at this temperature into the *trans*-form. Later, other investigators studied this conversion and the chromatographic separation not only of azobenzene but also of other azo compounds. It has been found in general that on alumina the *cis*-form is more readily absorbed than the *trans*-form, especially from petroleum ether solutions, the reverse being true on charcoal from methyl alcoholic solutions.

In another direction, too, these azo compounds are of considerable theoretical interest, particularly as to the structure of the hydroxy substituted products. In 1870, Friedrich Kekulé prepared *p*-hydroxyazobenzene, and for a time it was generally agreed that it was a true azophenol. In 1883, however, T. Zincke found that the compound formed by coupling phenyl diazonium ion with *α*-naphthol is identical with the one formed by condensing phenylhydrazine and *α*-naphthoquinone.



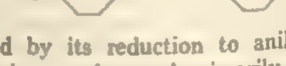
Investigation of this problem, whether the compounds have the azophenol (III) or the quinone-hydrazone structure (IV), has continued almost without a break since Zincke's discovery, and it is not yet solved. It now seems clear that the *p*-hydroxy compounds resemble the *meta* derivatives which can be prepared by an indirect method. Since the *meta* compounds cannot change into quinones but must be phenols, this is strong evidence that the *para* compounds are also true phenols. The *ortho* compounds differ from them in several ways. They are insoluble in alkalies and are not methylated even by such a vigorous agent as diazomethane. On the other hand, the *ortho* compounds cannot satisfactorily be allotted a quinone structure analogous to IV; *e.g.*, they are brominated and nitrated in a typically phenolic way. The anomalous behaviour of the *ortho* compounds must be connected with the proximity in space between the azo and hydroxyl groups. One result of this proximity is that hydrogen bonds can be formed either in the azo or hydrazone structure, as in V and VI.



V VI VII

There is the further possibility that the molecule may be the internal salt VII. Hence, there is strong presumption that the actual state of the molecule is that of a resonance hybrid of these three structures and that the *ortho* compounds cannot be said to have the simple structure either of an azophenol or of a quinone hydrazone. In the *para* series, structures analogous to V and VI are impossible, and thus the differences between the two series can be theoretically explained.

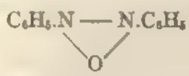
Aminoazo Compounds.—These are the normal products of coupling diazo compounds with aromatic amines. They are red, yellow, brown or deep-brown solids. Aminoazobenzene, known also under the trade name of Aniline Yellow, melts at 127° C. and can be distilled without decomposition under reduced pressures. Its structure,



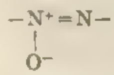
is clearly indicated by its reduction to aniline and *p*-phenylenediamine, and it is manufactured primarily as an intermediate for certain azo and induline dyes. The compound 2,4-diamino

azobenzene, $(NH_2)_2C_6H_3-N:N-C_6H_5$, made by coupling a mole of benzene diazonium chloride with a mole of *meta*-phenylenediamine, is sold in large quantities in world commerce as its hydrochloride under the name of Chrysoidine. Bismarck brown (Manchester brown), discovered in 1865, a mixture of tri- and tetraamino azobenzenes, being primarily benzene-meta-diazo-bis-metaphenylenediamine dihydrochloride, and made by the action of nitrous acid on *meta*-phenylenediamine in dilute hydrochloric acid, is well known in every industrial nation in the world as a brown dyestuff and stain.

Azoxy Compounds.—These form a small class of nonbasic substances produced, often very readily, in the reduction of aromatic nitro compounds. In this reaction they arise from the condensation of the nitroso compound and the substituted hydroxylamine, which are direct products of the reduction; this condensation takes place most readily in alkaline solution, so that with mild alkaline reducing agents azoxy compounds result in good yield. The first member of the class known was azoxybenzene, prepared in 1841 by N. Zinin by reducing nitrobenzene with alcoholic potash. Obtained by this method it forms yellowish crystals melting at 36° C. The molecular formula is $(C_6H_5)_2.N_2O$, and since it is readily reduced to azobenzene by heating with zinc dust, Kekulé suggested this structure:



This was accepted for many years, but in a series of investigations during the years 1910 to 20 A. Angeli showed that the azoxy group is not symmetrical, since oxidation of an azo compound with dissimilar radicals, $R-N:N-R'$, gives two isomeric azoxy compounds, $R-NO:N-R'$ and $R-N:NO-R'$. Hence, the structure of the group must be



a view supported by the fact that when azoxybenzene is nitrated or brominated only one ring is attacked, showing that the two rings are not linked to similar nitrogen atoms.

Since the azoxy group contains doubly linked nitrogen atoms, stereo-isomerism should occur as in the azo compounds (*see* above) even when the two attached aryl groups are identical. Such has been found to be the case.

AZORES (Açôres), an archipelago in the north Atlantic ocean comprising part of metropolitan Portugal. Area 894 sq.mi. Pop. (1960) 327,806. The islands extend from northwest to southeast, between 36° 55′ and 39° 43′ N., and between 25° and 31° 16′ W. They are divided into three widely separated groups, rising from a depth of more than 2½ mi. The southeastern group consists of São Miguel and Santa Maria, with Formigas; the central, of Faial, Pico, São Jorge, Terceira and Graciosa; the northwestern, of Flores and Corvo. The nearest continental land is Cape Roca in Portugal, which lies 740 mi. E. of São Miguel. Thus the Azores are farther from the mainland than any group of Atlantic islands. In general characteristics all the component islands are similar, rising steeply from scree- or talus-lined shores to heights reaching 7,713 ft. (in Pico). Their volcanic nature has been shown by the numerous earthquakes and basaltic eruptions that have taken place since their discovery. In 1522 the town of Vila Franca, at that time capital of São Miguel, was buried during a violent convulsion.

Climate.—The climate is very mild; the temperature ranges from 48° F. in January, to 82° F. in July, near sea level. West to northwest winds, sometimes stormy, prevail in winter; mild northeasters in summer. Meteorological data compiled and transmitted from the Azores are essential to European weather forecasting.

Vegetation and Animal Life.—The general character of the flora is decidedly European. Vegetation in most of the islands is remarkably rich, especially in grasses, mosses and ferns, heath, juniper and a variety of shrubs. There were almost no tall-growing trees until the 19th century when the Bordeaux pine, European poplar, African palm, Australian eucalyptus, chestnut, cryptomeria, elm, oak and many others were successfully introduced. The orange, apricot, banana, lemon, citron, Japanese medlar, apple and fig are the common fruits. Pineapples are cultivated extensively in greenhouses in São Miguel. Grapes and melons are abundant.

The mammals of the Azores are limited to the rabbit, weasel, ferret, rat (brown and black), mouse and bat, in addition to domestic animals. The game includes the woodcock, red partridge (introduced in the 16th century), quail and snipe. There are valuable fisheries of tunny, mullet and bonito. The porpoise, dolphin and whale are also common. Whale fishing is a profitable

Horta	296	49,194	Faial Pico Flores Corvo

industry throughout the islands whence the sperm oil is exported.

Economy and Communications.—The trade of the Azores was long a Portuguese monopoly, but later, before World War II, it was shared by Great Britain, the United States and Germany; textiles are imported from Portugal, coal from Great Britain. Other main imports are automobiles, mineral oils and machinery. Exports consist chiefly of hand embroideries, pineapples, canned fish and sperm oil.

In addition to regular mail services there are cables to both sides of the Atlantic, radio (telegraph and telephone) between the islands and to Europe. In 1939 a regular transatlantic air service was begun via the Azores. Civil aircraft use the airport at Santa Maria and military air traffic the air base at Lajes, Terceira.

Population and Administration.—The inhabitants of the islands are mostly of Portuguese origin. The predominant religion is Roman Catholic. The diocese of the Azores, founded in 1529, has its see at Angra. Two line regiments of infantry and two brigades of artillery as well as a regiment of the Portuguese air force are stationed in the islands. The most important island is São Miguel, noteworthy for scenery.

The Azores have no central government. The islands are grouped in three administrative districts with the same status as those of continental Portugal, but with special autonomous prerogatives exercised in each by a *junta geral.*

The principal seaports, which give their names to the districts, are Angra do Heroísmo, or Angra (pop. [1960] 13,929), Ponta Delgada (*q.v.*) (22,740) and Horta (7,250).

History.—The earliest notice of the existence of the Azores is found in some Italian and Catalonian maps of the 14th century, though the position of the islands was marked inaccurately. Claims that Carthaginian or other coins were found at Corvo have been dismissed as unfounded. According to the most reliable information the islands were discovered about 1427 by a pilot of the king of Portugal whose name was Diogo de Silves. No traces of human beings were found in any of them, nor even of their having been visited before. Settlement began in Santa Maria about 1432, under the guidance of Gonçalo Velho Cabral (not to be confounded with Pedro Alvares Cabral, who discovered Brazil in 1500). São Miguel was settled in 1444 and Terceira some years later. A few Flemings, under Jobs van Hurtere, were allowed to settle in Faial at the request of Isabella, duchess of Burgundy, who was the sister of Prince Henry the Navigator. The Flemings were absorbed by the Portuguese settlers and left no trace either in the language or customs of the population. By the end of the 15th century all the islands were inhabited and trade with Portugal became well established. When Philip II of Spain took possession of Portugal in 1580, the people of Terceira fiercely resisted the Spaniards and were only subdued two years later by a great Spanish fleet under the marquess of Santa Cruz. From then until 1640 the Azores, like the rest of Portugal, were subject to Spain. The Azores were the grand rendezvous for the fleets on their voyage home from the Indies; and hence they became a theatre of the maritime warfare between the English under Elizabeth I and the peninsular powers. One such expedition, which took place in 1591, led to the famous sea fight off Flores, between the English ship "Revenge," commanded by Sir Richard Grenville, and a Spanish fleet of 53 ships. Except for some time during the Spanish occupation there was no central government in the Azores until 1766 when the marquess of Pombal (1699–1782) established a governor and captain-general for the whole group at Angra, Terceira, to repress the abuses of the local administrators. When civil war broke out in Portugal, after Miguel had been proclaimed king in 1828, the constitutionalists in Terceira supported Pedro, the eldest brother of Miguel, and after an attack by the whole Portuguese fleet on the island was repelled at Praia, they succeeded with the aid of British mercenaries in entering Portugal and defeating Miguel. Maria da Glória, daughter of Pedro, was then acclaimed queen of Portugal. A new constitution was established in 1832 and the islands were grouped in three administrative districts (Ponta Delgada, Angra and Horta) which in 1895 were given autonomous administration within certain limits. In World War I the only incident in the islands was the attack on Ponta Delgada by a German submarine in 1917. A U.S. naval base was established at Ponta Delgada in World War I. In World War II Great Britain was allowed to establish an air base at Lajes airfield (Oct. 1943). Lajes and Santa Maria became important centres of military communications between the United States and Europe during World War II. Santa Maria airport was constructed for the U.S. air force in 1944 and the lease extended under the United States-Portuguese Defense pact, 1951. It was later transferred to Lajes.

AZORÍN (pseudonym of José Martínez Ruiz) (1874–1967), Spanish essayist, critic and novelist, remarkable for the subtle simplicity of his style, was born at Monóvar, Alicante, on June 8, 1874. As a member of the disillusioned "generation of 1898," which deliberately shunned the imposing and the obvious, he pursued his inspiration through half tones, muted colours and the subtleties of atmosphere. His early novels *La Voluntad* ("Volition"; 1902) and *Las confesiones de un pequeño filósofo* ("Confessions of a minor philosopher"; 1904) are tentative. But his most successful medium, both for critical and artistic purposes, proved to be the short essay in which, apparently artlessly, he creates the atmosphere of scene and leads his readers on by suggestion. Thus the spirit of old Castile is reconstructed in *El alma castellana* ("The Castilian soul"; 1900), the mind and environment of Cervantes' protagonist in *La ruta de Don Quijote* (1905) and literary criticism is conveyed obliquely through the seemingly inconsequent impressions of *Al margen de los clásicos* ("Marginal notes to the classics"; 1915) and *Rivas y Larra* (1916). The simplicity of his style attracted innumerable imitators almost all of whom failed to achieve Azorín's ideological subtlety, vitality and poetic rhythm. His later works include *De Granada a Castelar* (1922), *Una hora de España* (1924; Eng. trans., *An Hour of Spain*, 1931), the more abstract *Superrealismo* (1929) and numerous articles in periodicals. Azorín died in Madrid on March 2, 1967. (I. L. Mc C.)

AZOTUS: *see* Ashdod.

AZOV, a town and ancient fortress in Rostov *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., lies on the left bank of the main (southern) distributary of the Don, 20 mi. upstream from its mouth. It is a fishing port with fish canning, textile and agricultural machinery industries. Pop. (1959) 39,931.

The town was of great importance as a trading centre and fortress after its establishment in the 6th century B.C. as the Greek colony Tanais. Later a Genoese factory, Tana, it became a Turkish fortress, falling to Peter the Great in 1696 and finally being secured by the tsaritsa Anne in 1739. Since then, the port has silted and lost its functions to Rostov-on-Don, 16 mi. N.E. (R. A. F.)

AZOV, SEA OF (Azovskoye More), an inland sea off the southern coast of European Russia, forms an extension of the Black sea to which it is linked by the Kerch strait. Its area is 14,517 sq.mi., excluding the Sivash, or Putrid sea, which divides the Crimea from the mainland and which itself is separated from the Sea of Azov by a 66-mi.-long sand bar, the Arabatskaya Strelka. Its greatest length is 230 mi. and its greatest breadth 106 mi. The sea is shallow, with a maximum depth of 46 ft. Vast quantities of silt are brought down by the rivers Don and Kuban, and in the Taganrog gulf in the northeast depth is 3 ft. or less and deep draft vessels for Rostov and Taganrog have to transship in open roads. Depth varies markedly with wind force and direction, par-

ticularly in the Taganrog gulf. Salinity in the sea is low (1.1%) but in the Sivash it is very high (up to 10%). There is an anti-clockwise circular current along the coasts but this may be affected by winds. Fierce storms can occur and winds up to 65 m.p.h. have been recorded. The period of freeze up is variable but there is normally stationary ice along the northern coasts from the end of December to early March. With northeast and north winds the ice often breaks loose, to drift in the open sea. Coasts are low and characterized by long sandspits, shallow gulfs and lagoons in various stages of silting up. Fishing is extremely important, chiefly for sturgeon, bream, grey mullet, herring, Crimean anchovy and others. The major ports are Rostov-on-Don, Taganrog, Zhdanov, Osipenko, Genichesk and Temryuk. On the shores of the Sea of Azov, which was known in the ancient world as Palus Meotis, stood the Greek colony of Tanais, now Azov (*q.v.*). In the 19th century, the wheat trade was of great importance. Expeditions surveyed the sea in 1874, 1891, 1913 and 1922–28.

AZTEC, one of the most important Indian groups of the new world. The word *Azteca* is derived from Aztlán ("white land"), where, according to the Aztec traditions, their tribe originated. Aztlán probably is merely a general reference to the northwestern region of Mexico. The Aztecs are also known as Tenochca, a name derived from a legendary patriarch called Tenoch. Tenoch, or Tenochca, gave its name to Tenochtitlán ("stone rising in the water"), a city founded by the Aztecs on an island in Lake Texcoco, in the Valley of Mexico. The Aztecs or Tenochcas were also known as Mexica, probably derived from Meztliapan ("moon lake"), the mystical name for Lake Texcoco. The Aztecs themselves usually added the prefix *Culhua* to *Mexica* (Culhua-Mexica) in order to show their relationship to the most civilized peoples in the Valley of Mexico, whose centre was the city of Culhuacán. Mexica came to be applied not only to the ancient city of Tenochtitlán but also to the modern Mexican nation and its inhabitants (Mexico, Mexicans).

The language of the Aztecs was Nahua, part of the Uto-Aztecan linguistic family which, at the time of the discovery of America, was making its influence felt intermittently from western United States to Panamá. Once the Aztecs achieved political ascendancy, their language gained currency in an area almost as large as present-day Mexico. The Spanish conquerors, using Nahua as one of the principal means of communicating with Indians of other tongues, further extended the influence of the language. Approximately 1,000,000 people still speak Nahua in Mexico.

The empire the Aztecs established was equaled in the new world only by that of the Incas of Peru, and the brilliance of their civilization is comparable to that of other great ancient cultures of America and the old world. The story of their rapid rise and their dramatic fall has come down to us through the oral traditions preserved by the Aztecs and transcribed by the Spanish historians and ethnographers, through the Indian codices and through archeological testimony.

From their legendary land of Aztlán, the Aztecs came into contact with the highly developed Toltec (*q.v.*) civilization located in central Mexico and having as its capital the city of Tula (Hidalgo). The appearance of the Aztecs is linked, however, not to the splendour of Tula and of the Toltecs but to their decline. For reasons not yet fully known but having to do with internal social, political and religious conflicts, a tremendous cultural catastrophe, which has been compared to the fall of the Roman empire, occurred at the beginning of the 12th century A.D. The city of Tula was attacked and destroyed, as were other important Toltec centres. Tribes of less-developed cultures—hunters and gatherers—took advantage of the situation and added to the chaos, traveling from the arid plateau of northern Mexico toward the fertile, civilized central zone, pursuing and hastening the retreat of the more advanced agricultural peoples. In their legends the Aztecs like to portray themselves as part of that wave of barbarian invaders known by the general term Chichimecas ("sons of the dog"). The fact is, however, that the Aztecs were ancient "Toltequized" farmers, who for a long period had probably served as military aids to the Toltecs, precisely along the border which had separated them from the uncivilized Chichimecs and which had given way with the fall of Tula.

Throughout a century (from the beginning of the 12th century to the beginning of the 13th), the Aztecs wandered about in search of a new place to settle. During that time, a group of Chichimecs, under the leadership of Xólotl, succeeded in gaining power in the Valley of Mexico, establishing their centre first in Tenayuca and later in Texcoco. Xólotl's Chichimecs joined forces with the remaining Toltecs, who were firmly entrenched in Culhuacán. The combination of strong Chichimec power in rapid process of assimilating a higher culture and the restoration of Toltec power in Culhuacán led to a period of relative peace and cultural progress in the Valley of Mexico. The stabilization of this new situation attracted immigrants from all parts of the disturbed country, among them the Aztecs, who by then had established a precarious home near the ruins of Tula.

The Aztecs' stay in Tula was extremely eventful. On the one hand, they perfected their technological knowledge, especially with regard to agriculture. According to their traditions, it was there that they undertook irrigation cultivation and built *chinampas* (the famous and misnamed "floating gardens"); these techniques were to become essential in the foundation and survival of Tenochtitlán. On the other hand, the Aztec religion took definite form, with its god Huitzilopochtli ("Hummingbird-on-the-left"), its sun worship and its human sacrifice. Aztec tradition has it that Huitzilopochtli ordered them to take leave again in search of a permanent home.

The Aztecs' "pilgrimage" did not end with their arrival at the Valley of Mexico. For another century (until the beginning of the 14th) they were forced to wander about in unfriendly territory, suspected by their neighbours and harassed by their powerful opponents. Taking refuge in Chapultepec (modern Mexico City's main park), they fortified the hill for protection. Yet, after a battle that proved disastrous for them, the Aztecs were expelled from Chapultepec by a coalition of their neighbours, the Culhua-Toltecs of Culhuacán and the Tepanecs of Azcapotzalco. They then sought the protection of their Culhuacán conquerors and, in exchange for military service, received some land in Tizapán. It was not long before the ferocity shown by the Aztecs in war and their bloodthirsty religious rites alarmed the Culhuas, and once again the tribe was forced to take flight.

The pilgrimage was, however, nearly at an end. In the year of "two house," according to their calendar (A.D. 1325), the wanderers found the land spoken of in their prophecies. On a small island in Lake Texcoco, the elder members of the tribe spotted an eagle, symbol of the sun and of Huitzilopochtli, resting on a nopal. There they built the temple of their tribal god and, around it, the first dwellings of what was to become the powerful city of Tenochtitlán, the capital of the Mexica empire, of the viceroyalty of New Spain, and of the modern Mexican nation. Alongside, another Mexica group founded the twin city of Tlatelolco, which in time was to be absorbed by Tenochtitlán.

The swamp-surrounded island on which the Aztecs were forced to take refuge was so uninviting that none of the powers in the Valley of Mexico had claimed it. Tenochtitlán was thus located at the edge of the lands occupied by the valley's three powers: the Chichimecs of Texcoco, the Toltecs of Culhuacán and the Tepanecs of Azcapotzalco. It was not long before the Aztecs used their strategic position to advantage, placing their forces at the service of the Tepanecs, who proclaimed themselves heirs to the pre-Toltec civilization of Teotihuacán and who were emerging as the strongest power in the valley. It was as mercenaries and tribute-payers in the service of Azcapotzalco that the first three Aztec kings (Acamapichtli, Huitzilihuitl and Chimalpopoca) waged war against Culhuacán and Texcoco, thereby helping to establish the supremacy of the Tepanec king Tezozomoc. It was also as vassals of Azcapotzalco that the Aztecs participated in the campaigns that took them to what are now the states of Mexico, Morelos, Puebla, Hidalgo and Veracruz. In this way, the tribe began its apprenticeship as empire builders. Meanwhile, the city

AZTEC CALENDAR STONE SHOWING THE 20-DAY SIGNS IN INNER CIRCLE

of Tenochtitlán and the Aztecs were becoming prosperous through the spoils of war, trade and the acquisition of lands from conquered tribes.

During the reign of Itzcoatl, the fourth Aztec king (1427–40), a century after the founding of Tenochtitlán, dynastic differences were dividing the Tepanecs. Netzahualcoyotl, the legitimate king of Texcoco who had been dispossessed by the Tepanecs, returned to claim his rights, with the support of the powers of what are today the states of Puebla and Tlaxcala (Cholula, Huejotzingo, Tlaxcala). Aware of their newly gained strength and chafing under their dependence upon Azcapotzalco, the Aztecs allied themselves with the Tepanecs' enemies and helped bring about the fall of Azcapotzalco.

With the defeat of the Tepanecs by Itzcoatl and Netzahualcoyotl, hegemony over the Valley of Mexico was established by Tenochtitlán and Texcoco, with Tlacopan (Tacuba), a Tepanec city opposed to Azcapotzalco, holding the position of junior party in what has come to be known as the triple alliance. The agreement among the three powers provided for a five-way division of the spoils of war, two shares going to Texcoco, two to Tenochtitlán and one to Tacuba.

Mexica expansion was under way. As the military leaders of the triple alliance, the Aztecs consolidated their domination over the Valley of Mexico and over neighbouring areas in what are now the states of Morelos and Mexico. Under Huehue Moctezuma (Montezuma I), the fifth Aztec king (1440–69), the conquests were extended to the modern states of Guerrero, Hidalgo, Puebla and Oaxaca and, in another series of campaigns, to the Veracruz coast on the Gulf of Mexico. Moctezuma seems to have been a strong military leader and a weak political organizer. His successor, Axayacatl (1469–81), devoted most of his time as sovereign to putting down rebellions of recently conquered tribes, save for one invasion to the Pacific coast of the modern state of Oaxaca. The most important contribution made by Axayacatl to Mexica hegemony was the conquest of Tlatelolco, Tenochtitlán's twin city. The brief reign of Tizoc, the seventh Aztec king (1481–86), was merely a continuation of Axayacatl's efforts to preserve the empire.

Ahuitzotl, another great military leader and eighth king of the Aztecs (1486–1502), gave new impetus to Mexica expansion. His people not only consolidated their former territorial gains but extended their domain along the Pacific coast, from the mouth of the Balsas river to the present-day border between Mexico and Guatemala, and along the Gulf of Mexico, from the Tuxpan river to what is now the state of Tabasco. All the territory between these two coast lines fell to the triple alliance, whether by conquest or submission through fear of Ahuizotl's ferocious campaigns. Only two powers dared resist him: Tlaxcala, which was encircled by the Aztecs, and the Tarascan "kingdom," in the present-day state of Michoacán.

Ahuizotl's success as a military leader was not matched, however, by skill as an organizer. His campaigns seem to have been aimed less at extending the empire than at acquiring booty and tribute, capturing victims for sacrifice at Tenochtitlán and ruling by terror. The task of attempting to organize the empire along lines other than mere Aztec military strength and Ahuizotl-type terrorism was left to Moctezuma Xocoyotzin (Montezuma II, *q.v.*), the ninth Aztec king (1502–20). It was the reign of this second Moctezuma that produced the codices in which Aztec officials recorded the organization of the empire into provinces and the payment of tribute according to the production of each region. A gigantic political, military and religious bureaucracy was built up, with governors, tax collectors, courts of justice, military garrisons, mail and messenger services, etc. Despite their feverish efforts at political organization, the Aztecs still had the strength to subjugate their allies, Texcoco and Tacuba, and to undertake new campaigns. It is extremely probable that in this period Aztec troops pushed as far as Central America, into Guatemala and Nicaragua, just as Aztec merchants had done earlier.

But the days of the Aztecs' greatest glory were also their last. Since 1517, Spanish expeditions led by Hernández de Córdoba, Grijalva and Hernán Cortés (*q.v.*) had been exploring the coasts along the Gulf of Mexico. Rumours of ships as large as houses (*acalli*) reached the city of Tenochtitlán, and to them were added prophecies of the imminent return of the benign deity and cultural hero Quetzalcoatl; they could mean only disaster for the Aztecs and their god Huitzilopochtli. Cortés' bold march against Tenochtitlán set the stage for the final scene of the Aztec empire. Spanish might, combined with a general revolt of the peoples under Tenochtitlán domination, proved superior to the Aztecs' strength. Under the last two Aztec kings, Cuitláhuac and Cuauhtémoc, Tenochtitlán was besieged and destroyed, but only after a heroic Aztec defense. Over the still-smoldering ruins of Tenochtitlán a new city began to rise. Symbolizing the future Mexico, the Christian cathedral built there was erected on the stones of Huitzilopochtli's temple.

The almost incredible story of a small wandering tribe that was able to build an empire in one century (from the beginning of the 14th century to the beginning of the 15th) can be largely explained by three main factors: the Aztec religion, the economy of the Valley of Mexico and the sociopolitical organization of Mexica.

The Aztec religion was centred around the cult of Huitzilopochtli, a young warrior and symbol of the sun, who died every evening, to be born anew the following day. At dawn, Huitzilopochtli would begin his daily struggle against the stars and the moon, driving them away with a shaft of light. At sunset, he would die and return to the bosom of the earth, his mother (Coatlicue), where he would renew his strength in order to take up the fight against darkness, which was symbolized by his brothers, the stars, and his sister, the moon. If he was to permit this daily cycle to occur and guarantee human existence, Huitzilopochtli had to be well nourished, vigorous and healthy. His sustenance was human blood, life's precious liquid (*chalchiuatl*). The Aztecs were people of the sun, chosen by Huitzilopochtli to provide him nourishment. War was, therefore, their favourite occupation and religious obligation. In war they captured their enemies and sacrificed them to the sun, opening their chests and tearing out their hearts barehanded. As the Aztec power grew, the number of human sacrifices increased. Prisoners from all parts of the country were put to death in Tenochtitlán so that the universe and man might survive. The Aztecs' cult of the sun was not to go unrewarded; Huitzilopochtli therefore promised them no less than domination of the world. The Aztec empire was given the name *Cem-Anáhuac Tenochca tlalpan*, that is, "the world, land of Tenochca," and their king was called *Cem-Anáhuac tlatoani*, that is, "ruler of the

world."

If the Aztecs' religious conception and their belief in predestination were factors behind Mexica imperialism, the sacrificial rites of sun worship were an instrument of terrorism which the Aztecs wielded with unmerciful relentlessness. The chroniclers report that at the festivities inaugurating the reign of Ahuizotl, the most warlike of the Mexica leaders, 80,000 prisoners were sacrificed at Tenochtitlán, their hearts placed before the sun, their limbs served at ritual banquets and their mutilated bodies thrown to wild beasts. When there was no war and victims were scarce, the Aztecs organized a *xochiyaóyotl* ("war of the flowers") in order to capture prisoners for sacrifice to the sun.

The economic basis of the Aztec hegemony was the Valley of Mexico's agriculture, characterized by *chinampas* cultivation and irrigation systems. It was mainly from the Toltecs that the Aztecs had learned these techniques. Nevertheless, these methods date even further back in Mexican history; almost certainly they were in existence in the 6th century B.C. The high productivity of the systems resulted in a heavy density of population in the Valley of Mexico and the development of large urban centres. In the early 16th century the total population of the valley fluctuated around 2,000,000, cities like Tenochtitlán, Texcoco, Tacuba and Xochimilco approaching or exceeding the 100,000 mark.

Because of this enormous concentration of population and economic resources, the Valley of Mexico became the pivotal key to power in the central part of the country. The group successful in uniting the valley under a single authority could go on to conquer the neighbouring valleys of Morelos, Mexico, Puebla and Hidalgo, and, thence, the rest of the country. This seems to have been the cycle of unification of the valley, conquest of its outlying areas and expansion to the rest of Mexico that had been followed by the Teotihuacans and the Toltecs, who preceded the Aztecs in quest of empire.

From very early times, another factor contributed to the strategic importance of the Valley of Mexico and to the realization of its potential in terms of power: a system of lakes (Texcoco, Chalco, Xochimilco, Xaltoca and Zumpango) that were connected naturally and by means of artificial canals (*acalotes*). The transport facilities provided by the lakes and canals compensated for the difficulties resulting from the nonexistence of the wheel and of domesticated animals and, in no small measure, furthered the early economic and political unification of the valley. According to Spanish chroniclers of the time, there were no less than 200,000 watercraft in existence in the 16th century.

The concentration of population in the Valley of Mexico, the urban development, the possibilities of water transport and the geographical diversity of the neighbouring areas all served as powerful stimuli to trade. Probably in keeping with an ancient tradition, the merchants (*pochteca*) of Aztec society were organized in very powerful guilds, which even started wars on their own and sent trading expeditions to remote places. It was on the basis of the geographical data collected by their merchants that the Aztecs drew up maps not only of what is now Mexico but also of Central America. It is virtually impossible to separate the Aztecs' trade policy from their military and expansionist policy. In fact, the coming of the merchants announced the arrival of the Aztec warriors, and the trade system was not long in being replaced, in the event of conquest, by a system of taxation and control that channeled toward the Valley of Mexico part of the products of the region and the benefits of its trade.

The third essential factor in Aztec imperialism, one that was closely linked to the religious ideology and the economic conditions of the Valley of Mexico, was the sociopolitical organization of the tribe. Aztec society in the early 16th century displayed many features described as "primitive," together with manifestations of a highly advanced civilization. For example, the division of the tribe into *calpulli* ("big houses"), pseudo-family units established in Tenochtitlán, has sometimes been interpreted as proof of a classical equalitarian organization. Yet, evidence of social stratification is indisputable. Possibly the Aztecs retained the *calpulli* mainly because of their usefulness in military and political organization, at the same time as a system of social stratification was developing. The *calpulli* may, in fact, be defined as localized units of fictitious kinship, of ambilateral descent, having an endogamous tendency and showing true social stratification.

Aztec society has also been interpreted as "feudal." This assertion is based on the existence of an Aztec hereditary "nobility" (*tlatoque*), behind which was a group of knighted commoners (*tecuhtin*) with access to land rights. Nevertheless, the relation of these noble groups to the Aztec kings, to the rest of society and to land ownership cannot be compared with old world feudalism. At the time it came into contact with the Spaniards, Aztec society was characterized by an oriental-type political organization, in which the king was an absolute or autocratic despot in the process of deification. Particularly during the reign of the second Moctezuma, Aztec society and the empire itself were being vigorously reorganized, following a pattern that seems to be traditional in the Valley of Mexico. A gigantic bureaucracy, completely dominated by the king, was charged with administering the immense Aztec empire, its tributaries and its trade. The imperial bureaucracy gradually absorbed the old social groups of "nobles," "knights" and merchants.

AZUA, a province in southern Dominican Republic, crossed by the Sierra de Ocoa. Area 938 sq.mi.; pop. (1960) 75,147. In spite of low rainfall, agricultural production is abundant because of irrigation. The most important cultivations are coffee in the wetter mountainous areas, maize, plantains, bananas, peanuts and some sugar cane and tobacco. Lumbering of hardwoods and stock raising are significant. The province was established in 1845 and formerly had a larger area. The capital, Azua de Compostela (pop. [1960] 12,350), was founded in 1504 on the coast but was moved three miles inland after being destroyed by earthquake. (D. R. D.)

AZUAY, a province in southern Ecuador, bounded north by Cañar, east by Oriente, south by Loja and west by El Oro and Guayas. Its area is 3,011 sq.mi., and its population (1960 est.) was 329,900. The population is concentrated in the Basin of Cuenca (about 8,500 ft. above sea level) where farmers grow highland crops such as wheat, barley, potatoes and maize. Sugar cane, coffee and cotton are grown in the lower valleys. There is also a considerable amount of land used for the pasture of dairy cattle and, at higher elevations, of sheep. In the bordering mountains there are marble quarries and small-scale mining of gold, silver, mercury and platinum. Cuenca (*q.v.*), third largest city of Ecuador, is the capital of the province, and is the commercial centre of a large part of southern Ecuador. The manufacture of Panama hats from straw sent up from the lowlands is an important industry. (P. E. J.)

AZUELA, MARIANO (1873–1952), Mexican novelist, best known for his novels of the Mexican revolution, was born in Lagos de Moreno, Jalisco, on Jan. 1, 1873. He received an M.D. in Guadalajara in 1899, and practised medicine first in his native town and after 1916 in Mexico City. He wrote over 20 novels, mostly about the social effects of the Mexican revolution throughout its 30-year course. The most famous of these, *Los de abajo*, depicting the horrors of the revolution, resulted from his service as army doctor with Francisco Villa in 1915. Forced to flee across the border to El Paso, Tex., he first published the novel as a newspaper serial (Oct.–Dec. 1915). Hardly noted, the novel was "discovered" in 1924. It widely influenced other Mexican novelists of social protest, and was translated into most major languages, including English (*The Under Dogs*, trans. by E. Munguía, illus. by J. C. Orozco, 1929).

Returning from Texas to Mexico City in 1916, Azuela, disillusioned with the revolutionary struggle, wrote novels critical of the new regime: *Las moscas* (1918) and *Los caciques* (1917; Eng. trans. by L. B. Simpson, *Two Novels of Mexico: The Flies, The Bosses*, 1956); *Las tribulaciones de una familia decente* (1918).

His complete works in three volumes, edited by F. Monterde, appeared in 1959.

Azuela died in Mexico City, March 1, 1952.

See John E. Englekirk and L. B. Kiddle, Introduction and bibliographies in *Los de abajo*, pp. xi–lviii (1939). (L. Ll.)

AZURARA, GOMES EANES DE: *see* Zurara, Gomes Eanes De.

AZURITE or Chessylite, a basic copper carbonate, is found in nearly all copper mines, and is one of the ores of copper (*q.v.*). Its vivid blue colour contrasts strikingly with the emerald-green malachite, which it usually accompanies. It was known to Pliny as *caeruleum*. Azurite occurs with malachite in the oxidized portions of copper lodes, being due to alteration of copper sulfides by meteoric waters. It is often formed also by reaction between copper-bearing solutions and limestone and is a corrosion product of bronze.

The name chessylite is taken from Chessy, near Lyon, where many fine crystals belonging to the monoclinic system have been found. The formula is $2CuCO_3.Cu(OH)_2$. Hardness is 3.5 to 4 on Mohs' scale (*q.v.*) and specific gravity 3.8.

B THIS letter, corresponding to Semitic *beth* and Greek *beta*, has from earliest times retained the second place in all the European alphabets except the Cyrillic. Its form in the writing of the Moabite Stone, dating from the 9th century B.C., was . Early Greek forms were , and . The usual Greek form was or B, and in Latin the last two forms appear unchanged, giving the modern B. An uncial form occurs in the 6th century A.D. strangely resembling the early Greek forms from the island of Thera, but there can scarcely be a direct connection, the two similar forms having developed independently. (*See* ALPHABET.)

The equivalent Hebrew letter is thought to derive from an earlier symbol resembling the floor plan of a house; hence, the letter was named *beth*, the Hebrew word for "house."

The English minuscule form *b* is a descendant of Latin cursive . In this form the upper loop is extremely elongated and has almost disappeared. The early Irish form was ; the Carolingian (9th or 10th century) . The sound represented by the letter is the voiced bilabial stop. It stood for this sound in the Semitic languages and in Greek and Latin. From the 2nd century A.D. the sound in Latin tended to become a bilabial spirant for there is evidence of confusion in spelling between *b* and *u*. The letter, however, did not fall into disuse and was used in the Romance languages to represent the voiced labial stop in those situations where it was preserved, including the double *bb* and, in many of the languages, the initial *b*. The sound was always present in English, where it was derived from an original Indo-European **bh*.

The systems of phonetic changes involving the letter *b* in words of Germanic origin are discussed in GERMANIC LANGUAGES.

The Cyrillic alphabet was based on medieval Greek, in which the phonetic value of B had become *v*. A new form, , was therefore devised as the phonetic equivalent of *b*, and this letter appears in the second position of the Cyrillic alphabet.

In music, B is the second note of the musical alphabet and the seventh degree of the "natural scale" of C. In Germany, however, the alphabetical name for this note is, not B, but H, while B stands for B flat, a fact which is important to remember in dealing with German music, German writings on music and so on. Thus in German nomenclature Schubert's *Unfinished Symphony* is not in B minor but in H moll (minor), while Brahms's Second Pianoforte Concerto stands as being not in B flat but in B.

In chemistry, B is used as a symbol for boron. (J. W. P.)

BAADE, WALTER (1893–1960), German astronomer who became a resident in the United States in 1931, had a strong influence on galactic and extragalactic research. Born at Schröttinghausen on March 24, 1893, he was educated at the universities of Münster and Göttingen. During 1919–31 he was a member of the staff at Hamburg observatory. From 1931 to 1938 he was astronomer at Mount Wilson observatory in California. He returned to Göttingen as Gauss professor in 1959, and died there on June 25, 1960. The greater part of his observational and theoretical work is concerned with extragalactic nebulae as stellar systems. His main subjects are: variable stars in our galaxy, in globular clusters and in the Andromeda nebula; galactic and extragalactic novae; the investigation of the new star class of supernovae; the observation of the galactic nucleus through "galactic windows" (regions of low interstellar absorption near the galactic belt); the revision of the zero point of the period-luminosity curve of δ Cephei stars and the change in the cosmic distance scale by a factor two; the emission and absorption nebulae along the arms of spiral systems; the resolution of central parts of the Andromeda nebula; and the evidence for existence of two essentially different stellar populations of older and younger stars. Baade immensely stimulated the theory of stellar interiors as the basis of theoretical interpretation of stellar evolution. (O. H. L. H.)

BAADER, FRANZ XAVER VON (1765–1841), German theologian, was born at Munich on March 27, 1765. In 1826 he was appointed professor of philosophy and speculative theology at the new University of Munich, but in 1838 he ceased to lecture owing to a ministerial order prohibiting laymen from lecturing on philosophy and theology. He died at Munich on May 23, 1841.

The facts that Baader left no systematic works and that he usually expressed himself in obscure aphorisms or mystical symbols make it difficult to summarize his philosophy. He believes that reason must be supplemented by faith and church tradition and that it must clarify the truths given by authority and revelation. But in his attempt to correlate the two realms he approaches the mysticism of Eckhart, Paracelsus and Böhme. Human knowledge is never mere *scientia*, it is invariably *con-scientia*—a knowing with a consciousness of God whose knowledge compenetrates ours. God is not to be conceived as mere abstract Being, but as an everlasting process of activity, which is distinguishable under two aspects—the immanent or esoteric, and the emanent or exoteric. As regards ethics, Baader rejects the Kantian or any autonomic system of morals. Not obedience to a moral law, but realization in ourselves of the divine life is the true ethical end. But because man has alienated himself from God no ethical theory that neglects the facts of sin and redemption (and the necessity of prayer and the sacraments) is satisfactory. The history of man and of humanity is the history of the redeeming love of God. Man in his social relations is under two great institutions. One is temporal, natural and limited—the state; the other is eternal, cosmopolitan and universal—the church. In the state two things are requisite: first, common submission to the ruler, which can be secured or given only when the state is Christian, for God alone is the true ruler of men; and, second, inequality of rank, without which there can be no organization. A despotism of mere power and liberalism, which naturally produces socialism, is equally objectionable. The ideal state is a civil community ruled by a universal or Catholic church, the principles of which are equally distinct from mere passive pietism, or faith that will *know* nothing, and from the Protestant doctrine, which is the very radicalism of reason.

Baader's *Sämtliche Werke* were published in 16 volumes (1851–60). Some of his lectures at Munich were published under the title *Spekulative Dogmatik* (1827).

BIBLIOGRAPHY.—The most complete account of his thought is Eugene Susini, *Franz von Baader et le romantisme mystique*, 3 vol. (1942). A brief biography is that of Josef Siegl, *Franz von Baader* (1957). *See* also F. P. Siegfried in *Catholic Encyclopaedia*, vol. ii, pp. 173–175.

(J. J. PN.)

BAAL, the name of a god in many ancient near eastern communities, especially among the Canaanites, who apparently considered him the most important god in the pantheon. His name is common to the Semitic languages and means "lord" or "owner," but it could be used more generally: a *baal* of hair is an owner of hair, a hairy man (II Kings i, 8), and a *baal* of wings is a winged creature; in the plural, *baalim* of arrows is archers (Gen. xlix, 23) and *baalim* of oaths means conspirators (Neh. vi, 18). His name might be used to refer to a god bearing another name, even Yahweh himself, as is indicated by the occurrence of such names as Jerubbaal (Gideon), Ishbaal (one of Saul's sons) and Beeliada (a son of David, I Chron. xiv, 7). The last name appears in II Sam. v, 16 as Eliada, showing that El (God) was regarded as equivalent to Baal; *cf.* also the name Bealiah, "Yahweh is *baal*," which survives in I Chron. xii, 5. Yet such fluidity in the use of the term *baal* did not preclude its being attached to a god of distinct character, not only among other peoples but even by the Israelites.

Knowledge of Baal's personality and functions derives chiefly from a number of tablets uncovered in 1929 and later at Ugarit (*q.v.;* modern Ras Shamra) in northern Syria and dating from the middle of the 2nd millennium B.C. These tablets, although closely attached to the worship of Baal at his local temple, probably represent Canaanite belief generally. To them he was the god of the fertility of field and cattle who fought several enemies, died and was reborn. He was the Rider of the Clouds, deity of rain and storm, associated with the goddesses Little Lightning (the daughter of Light), Little Dew (the daughter of Distillation) and Little Earth. These divinities apparently have little individuality of their own and merely express aspects of Baal's power; of far greater importance is Anat, the warrior-goddess, who is Baal's consort and sister. His chief enemy is Mot, god of the rainless season and the nether world. By obvious symbolism the ascendancy of Mot on earth follows upon the death of Baal, who is buried together with huge sacrifices of all sorts of animals, and all activity on earth ceases. Anat, however, slaughters Mot, cuts him to pieces, burns, grinds and sows him in the fields. By this act she is doing what the farmer does to restore life to the earth; and as the farmer, his work over, prays for the return of the rain-god, so Anat, by the destruction and sowing of Mot, encompasses Baal's rebirth.

Other Ugaritic myths tell of the defeat by Baal of Yamm, a god of the sea, following a motif found in other near eastern stories in which a hero or younger god in the course of his adventures must defeat a sea monster. The myths tell also of Baal's struggle to obtain a palace comparable in grandeur with those of the other gods. He is opposed in this by El, chief of an older divine generation, and apparently also by El's wife Asherah. This myth must refer in part to the construction of Baal's own temple in the city of Ugarit, and may have been regularly recited in ritual commemoration of the temple's dedication. Near Baal's temple was that of Dagon, given in the tablets as Baal's father. Baal bears an alternate name, Hadad, taken from an old Semitic storm-god from whom Baal of Ugarit probably acquired much of his individuality.

Baal's worship was popular from the 14th century on in Egypt, where he was considered the counterpart of Setekh; through the influence of the Aramaeans, who borrowed the Babylonian spelling Bel, he ultimately became known as the Greek Belos, identified with Zeus. Of the worship of the Tyrian Baal, also called Melkart (King of the City) and often identified with the Greek Heracles but sometimes with Zeus, there are many accounts in ancient writers, from Herodotus on. He had a magnificent temple to which gifts streamed from all countries, especially at the great feasts; noteworthy is the annual feast of his awakening after the winter solstice. At Tyre, as among the Hebrews, Baal had his symbolical pillars, one of gold and one of smaragd (emerald), which, transported by fantasy to the farthest west, apparently gave rise to the familiar Pillars of Hercules. His name occurs as an element in Carthaginian proper names (Hanni*bal*, Hasdru*bal*, etc.), and a tablet found at Marseilles describes the charges made by the priests of the temple of Baal for offering sacrifices.

The Old Testament frequently speaks of the Baal of a given place, or refers to Baalim in the plural, suggesting the existence of local deities, distinct from one another, "lords" of the various locales. Yet these cannot have been merely vegetation spirits whose power extended no farther than the immediate vicinity. It is not known to what extent the Canaanites considered their various Baalim identical, but the Baal of Ugarit scarcely confined his activities to the town, and doubtless other communities agreed in giving him cosmic scope. Regarding Baal's importance the Old Testament may therefore be somewhat misleading, but concerning his functions it agrees fairly closely with the Ugaritic tablets. He is the source of all the gifts of nature; as the god of fertility, all the produce of the soil is his, and he receives tribute of the first fruits. Joined with the Baalim there are found corresponding female figures known as Ashtaroth, plural of Ashtoreth; here the Ugaritic and Hebrew sources apparently diverge, with Ashtoreth in the latter taking the place of Anat (*see* ASTARTE). The cult of the Baalim and Ashtaroth was characterized, in the eyes of hostile witnesses at any rate, by gross sensuality and licentiousness. On the summits of hills and mountains and "under every green tree" flourished the cult of the givers of increase. Human sacrifice (Jer. xix, 5), the burning of incense (Jer. vii, 9), violent and ecstatic exercises, ceremonial acts of bowing and kissing and the preparing of sacred mystic cakes appear among the offenses denounced by the Jewish prophets and suggest that the cult of Baal (and Ashtoreth) included characteristic features of worship which recur in various parts of the Semitic world.

The history of Baalism among the Israelites is obscured by the difficulty of determining whether the worship stigmatized by the prophets is the worship of Yahweh under a conception, and often with rites, which treated him as a local nature god; or whether Baalism was consciously recognized from the first to be distinct from Yahwism. The earliest certain reaction to Baalism is ascribed to the reign of Ahab, whose marriage with Jezebel led him to worship Baal and erect a temple to him in Samaria. This, however, did not prevent him from remaining a follower of Yahweh, whose prophets he still consulted, and whose protection he still cherished when he named his sons Ahaziah and Jehoram ("Yah [weh] holds" and "Yahweh is high"). Elijah, in crusading against this introduction to Israel of Baal's worship, certainly regarded him as no local vegetation spirit; his priests claimed for him the same power as Elijah for Yahweh. (*See* ELIJAH.) By the time of Hosea the antagonism to Baalism had so deepened that the use of the term "Baal" was felt to be dangerous to true religion. Thus there grew up the tendency to replace it by the contemptuous *bosheth* ("shame") in accordance with the idea of Ex. xxiii, 13; in compound proper names, for instance, may be found Ishbosheth for the earlier Ishbaal. Nonetheless, the books of Deuteronomy and Jeremiah afford complete testimony for the prevalence of Baalism as late as the exile, but prove that the Jews regarded it as debased as compared with the pure worship of Yahweh, the god of Israel. *See* BEL; *see* also references under "Baal" in the Index.

See A. S. Kapelrud, *Baal in the Ras Shamra Texts* (1952), with further bibliography. (W. M. SE.)

BAALBEK (BA'LABAKK), ancient Heliopolis (Greek "city of the sun"), is the principal town and agricultural centre of the rich plain of the Beka' the eastern district of the Republic of Lebanon. It stands at 3,850 ft., on the watershed separating the Litani (Leontes) and the Asi (Orontes), at the foot of Anti-Lebanon. Pop. (1956 est.) 11,700. Two-thirds are Mutawilis and one-third Christians and there are a few Sunnite Muslims. It is the seat of a Uniate Greek bishop. Baalbek is connected by railway and road with Beirut (40 mi. E.N.E.) and Damascus (35 mi. N.N.W.) via Riyaq (Rayaq), and with Aleppo, Syr. The main activities are agricultural, but there is some tourist trade.

History.—The name has given rise to conjecture; it was possibly connected with the worship of Baal (*q.v.*), the lord of the Beka' (R. Kittel, O. Eissfeldt). No remains or testimonies are earlier than the Greek conquest of Syria (333 B.C.). After the death of Alexander, the Beka' fell to Ptolemy and his descendants, under whom, presumably, the town was named Heliopolis after its Egyptian namesake. In 200 B.C. it was conquered by Antiochus the Great and remained a Seleucid possession until the fall of that dynasty. Around 65 B.C. it appears to have been

KAHOUS FROM YERVANT SARRAFIAN, BEIRUT

RUINS OF THE TEMPLE OF JUPITER, BAALBEK: COMPLETED 3RD CENTURY A.D.

under the sway of an Arab (Ituraean) chieftain, Ptolemy (son of Mennaeus), whom Pompey, when he occupied Heliopolis in 63 B.C. on his way from Antioch to Damascus, confirmed as a vassal prince against payment of a large sum. In 36 B.C. it belonged to the Syrian territories donated by Marcus Antonius to Cleopatra. About 16 B.C., Augustus settled veterans of two legions in Baalbek under the name Colonia Iulia Augusta Felix Heliopolis.

The two huge temples could only have been built on imperial initiative and with imperial funds, probably to provide a common religious centre for the colonists and the native population. The temple of Jupiter was erected under the Julio-Claudian dynasty, but it took about two centuries to complete its elaborate courtyards. Trajan, on his way to the Parthian War, consulted the oracle of Jupiter Heliopolitanus, who is said to have foretold his death in terms that were only understood after the event. The temple of Bacchus was probably built around A.D. 150. The eviction of pagan by Christian religion seems to have been a gradual one; Constantine (d. 337) is supposed to have closed the temples; Theodosius I (379–395) is said to have established a church in the temple, but the great basilica that was built over the altars in the courtyard cannot be earlier than the 6th century. Baalbek passed under Arab domination in 637 ('Omar I) and remained under the caliphs until 1075, when it fell under the rule of the Seljuks. From 1110 it was subject to their vassals, the Burids; in 1136 it fell into the hands of Zangi, prince of Aleppo. In 1157 it was conquered by Nureddin, who, in 1170, rebuilt its walls after a destructive earthquake, and in 1174 it came under Saladin. The Mongols occupied the town in 1260 for a few months, and Baalbek became a possession of the Egyptian Mamelukes under whom it remained until the Ottoman conquest in 1517. After World War I the French mandatory authorities included Baalbek in the State of Lebanon, the present Republic of Lebanon.

Archaeology.—Although European attention was first directed to the ruins in the 16th century (Martin von Baumgarten 1507; Pierre Belon du Mans 1553), Robert Wood was the first to publish a good survey of the temples, with many plates (1757). From 1898 to 1905 a German expedition under Otto Puchstein excavated the temples. Extensive clearings and repairs were accomplished under the French mandate and the Lebanese government has undertaken considerable restoration work. The so-called acropolis includes the temples of Jupiter and Bacchus, with their entirely separate precincts. Access to the temple of Jupiter is gained by the propylaea (early 3rd century) leading to a hexagonal forecourt (middle 3rd century). The worshipers were then admitted to the main court (2nd century). There, flanked by two basins for lustral purposes, stood two huge altars (the larger one was 60 ft. high) erected in the 1st century and designed to allow people to worship from a height. The rectangular court, 343 × 338 ft., is surrounded by elaborately decorated exedrae (semicircular benches), opening on a portico whose 84 granite columns were brought from Aswan in upper Egypt. In the 6th century A.D. a Christian basilica, now removed, was built over the altars. At the western end of the court, on a high artificial terrace, preceded by an imposing stairway, stood the temple, a Corinthian building with 10 columns on each front and 19 on each flank. The terrace probably goes back to pre-Roman days; the temple, according to an inscription, was near completion in A.D. 60. Only six columns of the south side, with their beautifully carved entablature, are still standing (height 62 ft., diameter 7½ ft.). A more ambitious project of the early empire was to raise a high platform round the temple, but it had to be abandoned and its only remains are the formidable foundations to which belonged the famous trilithon of ancient writers (three blocks, each roughly 62 × 14 × 11 ft.). The temple was dedicated to the Heliopolitan triad which included (1) the Syrian thunder-god Hadad, equated with Jupiter; (2) the Syrian nature-goddess Atargatis, equated with Venus; and (3) a youthful god, probably a vegetation spirit, a protector of the crops and cattle, equated by the Greeks with Hermes the shepherd, hence by the Romans with Mercury. Originally the cult was purely agricultural. Like many such cults, however, and probably under Greek influence, it seems to have developed a mystic aspect, and the youthful god, in many respects not unlike Adonis, seems to have acquired some bacchic features. The cult was spread over the whole Roman empire, mainly by merchants and soldiers (*e.g.*, dedications found in Northumberland, Eng., along Hadrian's wall at Carvoran).

The Temple of Bacchus (middle of 2nd century A.D.), not so large, but almost entirely preserved, is also Corinthian, with 8 × 15 columns. Its symbolic decoration shows that it was dedicated to the same triad as the great temple, but the prevalence of bacchic symbols in the interior probably points to a mystic destination. Other ruins include (1) a round temple (3rd century), of unknown destination, near the acropolis; (2) remains of the city walls; (3) on the hill of Sheikh Abdullah, traces of a temple dedicated to Hermes; (4) important Roman mosaics from private houses, now in Beirut museum; (5) a ruined mosque with re-employed antique material; (6) extensive Arab fortifications, including a mosque, in the acropolis.

BAB (Mirza 'Ali Mohammed of Shiraz) (1820–1850), became the founder of a Muslim religious sect in 1844 when he claimed for himself the title of Bab ("gate") to the truth. The concept of a Bab who affords access to divine guidance is a familiar one from Shi'ite Islam, and Mirza 'Ali Mohammed was not the first to appropriate the title. The Shi'ites believe that the last of their great leaders or Imams, upon which they are dependent for spiritual direction, became invisible to his followers about A.D. 874. It is expected that he will return at some future time, but in the meanwhile contact with him is possible only through an intermediary known as the Bab (*see* Imam; Shi'ism). In the latter portion of his brief career, Mirza 'Ali Mohammed dropped the title Bab and proclaimed himself the Imam Mahdi whose coming the Shi'ites so long had expected. Many were willing to accept his claims, and a strong religious movement grew up about him. The movement met with sharp opposition from both orthodox Muslims and the Persian government. The founder was arrested on suspicion of insurrection, and there ensued a series of bloody clashes. The Babis were subject to persecution by the authorities, about 28 of them being executed after an attempt on the life of the Shah in 1852. Mirza 'Ali Mohammed was executed in 1850 after a career of only six years and passed his spiritual authority on to a young disciple, Mirza Yahya, known as Subh-i-Azal. *See* also Babism. (C. J. A.)

BABBAGE, CHARLES (1791–1871), English mathematician and mechanician, the originator of the modern automatic computer, was born at Totnes, Devon, on Dec. 26, 1791. He went up to Trinity college, Cambridge, in 1810. There, instead of taking the tripos, he founded, with Sir John Herschel and George Peacock, the Analytical society, whose object was to introduce continental developments into English mathematics, in particular by replacing the Newtonian *Dot* notation in the calculus by the Leibnizian *D* notation. In the years 1815–17 he contributed three papers on the "Calculus of Functions" to the *Philosophical Transactions*, and in 1816 was elected a fellow of the Royal society. He first had the idea of mechanical calculation of tables in the rooms of the Analytical society in 1812 or 1813. He later made a small machine which would tabulate to eight decimals a function whose second differences were constant, and in 1823 he obtained government support for a projected difference engine with 20 decimals working up to seventh differences. The design was sound, but its practical realization required much development of engineering techniques to which Babbage devoted himself. In 1826 he invented a new notation for drawings of machinery. But in 1842, after more than ten years' indecision, the government of Sir Robert Peel refused the further support which had been recommended by the Royal society, and Babbage's difference engine was never finished. A machine based on Babbage's ideas was made in 1855 by Scheutz, a Stockholm firm. Meanwhile, in 1834, Babbage invented the principle of the analytical engine, the automatic computer of the 20th century. He devoted many years of his life to the construction of this also, but it was never finished. From 1828 to 1839 Babbage was Lucasian professor of mathematics at Cambridge. He was instrumental in founding the Astronomical (1820) and Statistical (1834) societies, and published papers on mathematics, statistics, physics, machine design and geology.

Babbage's books include a translation of part I of *An Elementary Treatise on the Differential and Integral Calculus* by S. F. Lacroix (1816); *Reflections on the Decline of Science in England* (1830); *On the Economy of Machinery and Manufactures* (1832); the *Ninth Bridgewater Treatise* (1837); *Thoughts on the Principles of Taxation* (1848); and *Passages From the Life of a Philosopher* (1864).
See also H. P. Babbage, *Babbage's Calculating Engines* (1889). (G. A. B.)

BABBITT, IRVING (1865–1933), U.S. critic and teacher, was best known as the leader of the 20th-century movement in literary criticism known as the "new humanism," or neohumanism. Born in Dayton, O., on Aug. 2, 1865, he was educated at Harvard and at the Sorbonne in Paris. He was a teacher of French and comparative literature at Harvard from 1894 until his death on July 15, 1933.

A vigorous teacher, lecturer and essayist, Babbitt was the unrestrained foe of romanticism and its offshoots, realism and naturalism, opposing to these the classical virtues of restraint and moderation. Allied with Babbitt were Paul Elmer More, Norman Foerster and, for a time, Stuart P. Sherman. Such earlier followers as T. S. Eliot and George Santayana later criticized him adversely. (For other opposition, *see* also American Literature: *From 1914 to 1945*.)

Babbitt extended his views beyond literary criticism: *Literature and the American College* (1908) opposes vocationalism in education and calls for a return to the study of classical literatures; *The New Laokoön* (1910) deplores the confusion in the arts created by romanticism; *Rousseau and Romanticism* (1919) criticizes the effects of Rousseau's thought in the 20th century; *Democracy and Leadership* (1924) studies social and political problems; *On Being Creative* (1932) compares the romantic concept of spontaneity adversely with classic theories of imitation. The humanist and antihumanist controversy reached its peak shortly before the depression of the 1930s.

Bibliography.—Frederick Manchester and Odell Shepard (eds.), *Irving Babbitt, Man and Teacher* (1941); Frederick Manchester (ed.), *Spanish Character*, Babbit's posthumous volume of essays (1940), contains a bibliography.

BABBITT, ISAAC (1799–1862), U.S. inventor, was born in Taunton, Mass., on July 26, 1799. He was trained to be a goldsmith and thus had some opportunity to experiment with metals, in which work he succeeded in making the first britannia ware produced in the United States (1824). Ten years later he went to Boston and while employed there by the South Boston Iron Co., in 1839, he made one of the types of alloy known as Babbitt's metals, or white metals. They are hard compositions of tin with antimony and copper, and are used for bearings. For this invention he received a gold medal from the Massachusetts Charitable Mechanics' association and an award of $20,000 from congress. He became a manufacturer of this metal and of soap. He died in Somerville, Mass., on May 26, 1862.

BABBITT'S METAL, an alloy invented in 1839 by Isaac Babbitt for the special purpose of providing a suitable bearing material for steam engines. Babbitt's patent covered only the principle of using a soft conformable alloy supported by a stronger shell; the alloy mentioned in the patent contained 89 parts of tin, 9 of antimony and 2 of copper. Babbitt's metal had a two-phase structure consisting of hard particles in a soft matrix. It was theorized that the hard particles form a "pavement" which supports the load while the soft matrix is worn down to a level slightly below that of the hard "pavement" and thus provides a series of channels for supply of lubricant. The antimony strengthens the matrix by dissolving in the tin and by forming hard cubic particles of tin-antimony (SnSb) compound. Copper additions form hard needle-shaped particles of copper-tin (Cu_6Sn_5) compound which entrain the tin-antimony cubes and ensure uniform distribution.

The term Babbitt is widely used to include three groups of bearing alloys: high-tin alloys (substantially lead-free) containing 90% or more tin, high-lead alloys containing 70% or more lead and intermediate alloys containing tin and lead in the matrix. *See* Bearing Metals; Alloys.

See P. G. Forrester, *Babbitt Alloys for Plain Bearings*, Tin Research Institute Publication No. 149 (1950); C. H. Mathewson, *Modern Uses of Non-Ferrous Alloys*, "A.I.M.E. Series" (1953). (R. M. MacI.)

BABBLER, the general name applied to members of a large old-world family of birds (Timaliidae), the babbling thrushes. There are sometimes united with the thrush family (Turdidae). There are about 260 species, ranging in size from warbler to jay, some dull, some gaily clad. They are abundant in China and Malaysia, about 50 species being found in forests of the Malay peninsula. The best known are the Chinese robin (*Liothrix lutea*), the coachwhip bird (*Psophodes*) and the red-capped babbler (*Timalia pileata*) of southeastern Asia. (G. F. Ss.)

BABCOCK, STEPHEN MOULTON (1843–1931), U.S. agricultural research chemist, called the father of scientific dairying, was born Oct. 22, 1843, near Bridgewater, N.Y. He is best known for development of a simple method to measure the butterfat content of milk by mixing sulfuric acid with a measured sample of milk to liberate the fat globules, which, in a graduated container, indicate the percentage of butterfat at a glance. The Babcock test, introduced in 1890, discouraged watering and adulteration practices and enabled farmers to realize profits from milk according to the intrinsic fat richness of the product; it also gave major stimulus to improvement of dairy production through improvement of herds. Babcock studied at Tufts college, Medford, Mass., and Rensselaer Polytechnic institute, Troy, N.Y., and at the University of Göttingen, Ger. (Ph.D., 1879). After several years of working as a teacher and chemist in New York, Babcock joined the University of Wisconsin staff in 1888, remaining there 43 years. Pioneer nutritional studies, specifically vitamin research, for which the University of Wisconsin became famous, are credited to the Babcock laboratory, and at least ten other notable inventions and discoveries in his field were made by Babcock alone or with fellow workers. He repeatedly refused to patent his discoveries, preferring that the world benefit freely by them. He died July 2, 1931, in Madison, Wis.

See E. T. Dies, "Jolly Scientist," *Land*, 8:193–196 (1949).

BABEL, TOWER OF, according to Gen. xi a structure erected in the plain (or valley) of Shinar. Because of its builders' presumption in erecting a tower that reached the heavens—symbolizing human self-sufficiency and pride—the Lord confused their tongues. The myth on which the building of the tower rests may have developed as an attempt to account for the diversity of man's languages. Use of the word Babel perhaps indicates that the story was inspired by the Babylonian ziggurat of Etemenanki, north of the Marduk temple Esangila (*see* BABYLON). The "confusion" of tongues would be correctly indicated by *balal*, Heb. "to confuse."

See H. Gressmann, *The Tower of Babel* (1928); A. Parrot, *Ziggurats et tour de Babel* (1949).

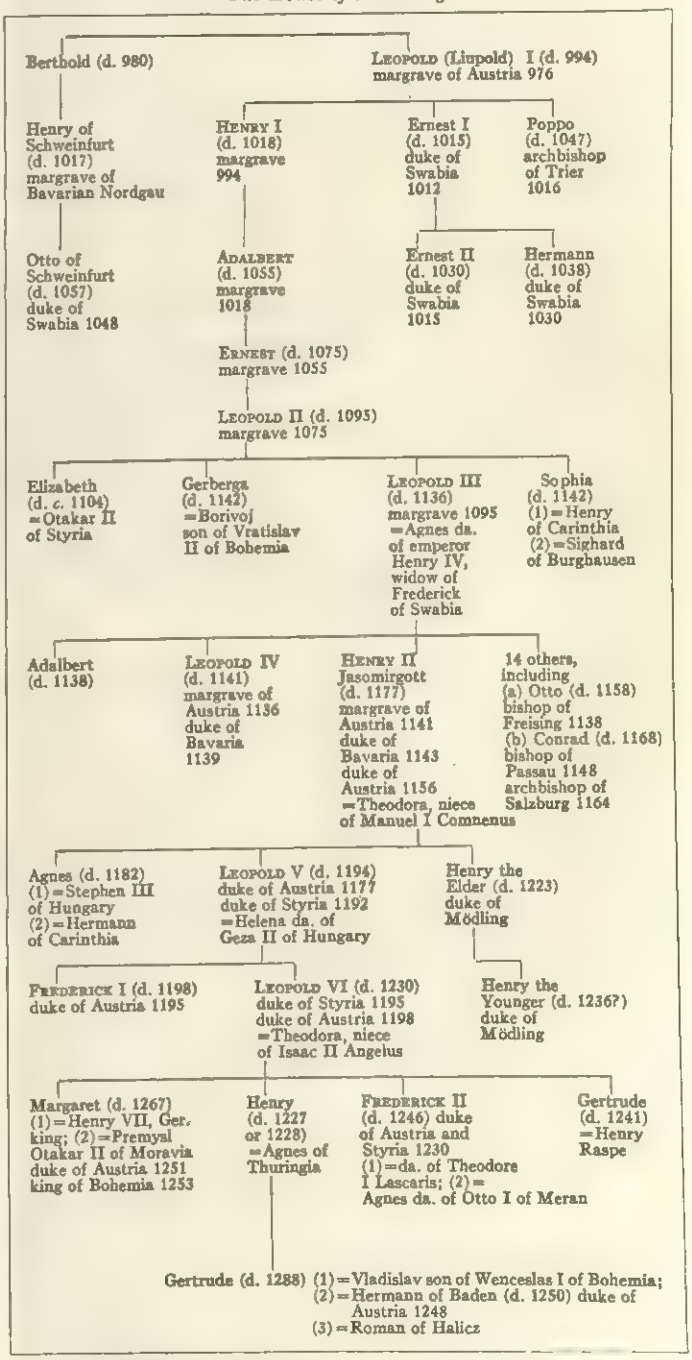
BABELL, WILLIAM (*c.* 1690–1723), English composer, known in his time as a keyboard executant of outstanding brilliance. Born about 1690, probably in London, he was taught music by his father (a bassoonist) and the eminent theoretician Dr. Pepusch, and he held appointments as organist of All Hallows, Bread street, and as an orchestral violinist. He is chiefly remembered for his virtuoso transcriptions for harpsichord of popular operatic excerpts, especially those based on arias from Handel's *Rinaldo*. His reputation as a performer was widespread and according to one German critic, he was said to surpass even Handel himself. He died on Sept. 23, 1723, in London. About two years later his friends arranged the publication of some of his compositions, comprising two sets of solo sonatas for violin, oboe or flute and *continuo*; though rather variable in quality and of no great originality, they often disclose a pleasing melodic gift and are of interest in that the ornamentation of the slow movements—usually left to the performer's discretion—is fully written out.

(S. J. SA.)

BABENBERG, the name of the first Austrian dynasty (976–1246), derived from the castle of Babenberg, first mention of which is made in 902 and which later became the bishopric and town of Bamberg in Franconia. The historian Otto of Freising reports that the family of Babenberg, of which he himself was a member, was descended from Count Adalbert (executed in 906). This would indicate that the family stemmed from the East Frankish family of the Poppones and that their ancestor was Poppo I, who in 819 was a count in the parts of Franconia bordering on Hesse. This Poppo's grandsons were probably the brothers Adalhart, Henry and the aforementioned Adalbert, who in the struggle for supremacy in Franconia against the Conradines (ancestors of the German king Conrad I) concentrated their forces on the castle of Babenberg. The conflict, however, ended in their defeat and death (for the first two in 902, for Adalbert in 906), and all their possessions were confiscated by the king, Louis the Child.

Modern research, however, has cast doubts on the descent of the Austrian margraves from this older Babenberg family; there are also grounds for supposing connections between the later Austrian dynasty and the Bavarian ducal house of the Arnulfings. But reliable information only becomes available in the Ottonian period. Berthold of Babenberg (*see* table) owned the northern countships of eastern Franconia by the time of the reign of the emperor Otto I, and his younger brother Leopold I (Liupold) received the Austrian mark in 976. At the borders of the Bavarian dukedom the brothers had to hold in check the supporters of Duke Henry the Quarrelsome, who had been deposed by Otto II. The accession to the German kingdom of Henry II (1002), son of the Quarrelsome, led to a rising under Berthold's son Henry of Schweinfurt, which cost him all his lands except his personal property in eastern Franconia. The last of this elder line, Otto of Schweinfurt, in recognition of services to the German king Henry III, received the dukedom of Swabia (1048–57), which had previously (1012–38) been held by Leopold's descendants. From

The House of Babenberg



(1) (2)=Indicates order of marriage.

1036 to 1038 the Babenberg duke Hermann of Swabia had extended his rule to the mark of Turin, through marriage with the daughter of its margrave, Manfred II (d. 1035).

Although the position of the house of Babenberg in the Austrian mark was for long only a modest one, they enjoyed a considerable standing as a result of their family connections. The wife of Leopold I was probably a niece of the emperor Otto II, and his grandson the margrave Adalbert is reported to have married a sister of King Peter of Hungary. Leopold II's daughters married the dukes of Carinthia and Bohemia and the margrave of Styria. Leopold III was the brother-in-law of the emperor Henry V and after the latter's death (1125) was a candidate for the German crown. He was the most important of the Babenberg margraves and was soon venerated by his people as a saint (canonized in 1485).

Among the sons of Leopold III, Henry II Jasomirgott and the historian Otto of Freising are the most notable. They were half brothers of King Conrad III, and in their generation a number of marriages forged connections between the house of Babenberg and the Welfs, Hungary, Bohemia, Poland, Montferrat (Piedmont) and Byzantium. Leopold IV and Henry were both dukes of Bavaria, and in 1156 Austria was raised to a dukedom (*see* AUSTRIA, EMPIRE OF). In 1192 Leopold V succeeded to the dukedom of Styria; his part in the third crusade brought him into conflict with Richard I of England and led to the unlawful imprisonment of the king, whose niece Eleanor it was intended should marry one of Leopold's sons (1193). The ransom for Richard's liberation was used partly for the foundation of Wiener Neustadt (1194) and its fortification against the Hungarians, and partly for the reform of the Austrian currency.

In the 12th century the Babenbergs were in fact the rulers of the country, far overshadowing the rest of the Austrian nobility, whose political powers they steadily reduced. The period of their greatest power was under Leopold VI. Leopold's son Frederick II engaged in conflicts with the Bavarians, Bohemians and Hungarians and, after the fall of his brother-in-law the German king Henry VII (the emperor Frederick II's son), was temporarily dispossessed of his lands. The duke's two marriages remained childless; in 1245 it was arranged that his niece Gertrude should marry the emperor Frederick II and that Austria should be raised to a kingdom, but these plans were not realized. Duke Frederick was killed on June 15, 1246, fighting against the Hungarians on the Leitha river. For Margaret, his sister, and for Gertrude, who both survived him, *see* AUSTRIA, EMPIRE OF.

BABEUF, FRANÇOIS NOEL (GRACCHUS BABEUF) (1760–1797), French political agitator who attempted to overthrow the Directory and to set up a communist "republic of equals," was born at St. Quentin on Nov. 23, 1760. From 1785 until the outbreak of the French Revolution he was employed as *commissaire à terrier* at Roye, with the invidious duty of assisting landlords to assert their feudal rights over the peasants. In 1789, however, he drew up the first article of the *cahier* of the electors of the *bailliage* of Roye, demanding the abolition of feudal rights (*see* FRENCH REVOLUTION).

During the earlier period of the Revolution Babeuf served in various minor posts in Paris or in the provinces. In 1794, however, he settled in Paris and on Sept. 3 published the first number of his *Journal de la liberté de la presse*, renamed *Le Tribun du peuple* in the following October. In this paper he vehemently attacked the men of the Terror, who had been overthrown by the *coup d'état* of Thermidor, and at first defended the Thermidorians. But he also attacked the economic outcome of the Revolution and later the Thermidorians themselves. As a result of this Babeuf was arrested in Feb. 1795 and sent to prison at Arras. There he came under the influence of certain terrorist prisoners, notably R. F. Lebois, editor of the *Journal de l'égalité*. He emerged from prison a confirmed communist, convinced that his utopia could only be realized through the restoration of the constitution of 1793.

The misery due to the fall in value of the *assignats* gained Babeuf a hearing. He gathered round him a small circle of his immediate followers, known as the Société des Égaux. This was soon merged with discontented Jacobins who met near the Panthéon. After the club of the Panthéon had been closed by Bonaparte (Feb. 29, 1796), Babeuf's activity increased, and on April 11, 1796, Paris was placarded with posters headed *Analyse de la doctrine de Baboeuf*, inciting people to revolt against the Directory. The Babouvist song "Mourant de faim, mourant de froid" ("Dying of hunger, dying of cold") began to be sung in the *cafés* with great applause, and reports were current that the disaffected troops in the camp of Grenelle were ready to join a rising against the government.

The Directory thought it time to act. Its agents, notably the former captain Georges Grisel, who had been initiated into Babeuf's society, had produced complete evidence of a Babouvist and Jacobin conspiracy for an armed rising fixed for 22 Floréal year IV (May 11, 1796). On May 10, 1796, Babeuf was arrested with many of his associates, including A. Darthe, P. M. Buonarroti and L. Taffoureau, together with four former members of the Convention, Robert Lindet, J. A. B. Amar, M. G. A. Vadier and J. B. Drouet. The trial of Babeuf and his accomplices was fixed to take place before the newly constituted high court of justice at Vendôme. On 7 Prairial year V (May 27, 1797), Babeuf and Darthé were condemned to death, while the rest were either exiled or acquitted. Babeuf and Darthe, on hearing the verdict, attempted to commit suicide, but were nevertheless executed at Vendôme on 8 Prairial.

Babeuf and his followers wanted the return of the constitution of 1793 because it had been a democratic constitution established by the vote of the French people and as such could provide a rallying point for all parties among the discontented revolutionaries. They regarded the arbitrary destruction of this constitution in 1795 as illegal and those who supported its destruction as traitors. Yet the Babouvists attacked the right to property which had been reaffirmed in the constitution of 1793. The opening sentences of the *Analyse de la doctrine de Baboeuf* declared that: "Nature has given to every man the right to the enjoyment of an equal share in all property." Babeuf moreover maintained that a true state should contain neither rich nor poor, but imposed upon every man an obligation to work. The Babouvists' disappointment at the outcome of the Revolution is made clear in another sentence from the *Analyse*: "The Revolution is not yet complete, because all the good things of life are taken by the rich, who rule as dictators, while the poor toil in misery like slaves and are considered of no account in the state."

BABIES, CARE OF: *see* INFANTS, CARE OF; MATERNAL AND CHILD HEALTH.

BABINGTON, ANTHONY (1561–1586), English conspirator, was one of the principals in a plot to assassinate Elizabeth I, secure the release of Mary Stuart and promote a general rising of Roman Catholics in England. The son of Henry Babington of Dethick in Derbyshire and of Mary, daughter of Lord Darcy, he was born in Oct. 1561 and was brought up secretly a Roman Catholic. As a youth he served at Sheffield as page to the earl of Shrewsbury, keeper of Mary Stuart, for whom he early felt an ardent devotion. In 1580 he went to London, attended the court of Elizabeth I and joined the secret society supporting the Jesuit missionaries. In 1582, after the execution of Edmund Campion, he withdrew to Dethick, and later went abroad. He became associated at Paris with Mary's supporters, who were planning her release with the help of Spain, and on his return he was entrusted with letters for her. In May 1586 he was joined by the priest John Ballard in the plot which generally bears his name. The conspiracy, in its general purpose of destroying the government, included many Roman Catholics and had ramifications all over the country. Philip II of Spain promised immediate assistance with an expedition after the assassination of the queen was effected. Babington wrote to Mary explaining his plans, but his

letters and her reply were intercepted by the spies of Sir Francis Walsingham. On Aug. 4 Ballard was seized and betrayed his comrades, probably under torture. Babington had already applied for a passport abroad, for the ostensible purpose of spying upon the refugees, but in reality to organize the foreign expedition and secure his own safety. The passport being delayed, he offered to reveal to Walsingham a dangerous conspiracy, but the latter sent no reply, and meanwhile the ports were closed.

Shortly afterward, Babington is said to have observed a memorandum of Walsingham's concerning himself while in the company of the minister's servants. Thereupon he fled to St. John's Wood and after disguising himself succeeded in reaching Harrow, where he was sheltered by a Roman Catholic convert. Toward the end of August he was discovered and imprisoned in the Tower of London. On Sept. 13–14 he was tried with Ballard and five others by a special commission; he confessed his guilt but strove to place all the blame upon Ballard. All were condemned to death for high treason. On Sept. 19 he wrote to Elizabeth praying for mercy, and the same day offered £1,000 for procuring his pardon; the next day he was executed in Lincoln's Inn Fields.

The historical significance of the Babington plot lies in its implication of Mary Stuart. The only positive documentary proof that Mary had knowledge of the intended assassination of Elizabeth is in a postscript to her final answer to Babington. The authenticity of this postscript has been challenged, but it is argued that Mary's circumstances, together with the tenor of her correspondence with Babington, place her complicity beyond all reasonable doubt. *See* also MARY (Mary Stuart).

BABIRUSA, the wild East Indian swine of the Celebes and Buru (*Babirussa babyrussa*). Its stout body is covered with a rough gray hide, almost devoid of hair. The peculiarity of this hoofed mammal is the exaggerated development of the canines, or tusks, of the male. Those of the upper jaw are directed upward from their bases, so that they never enter the mouth, but pierce the skin of the face and curve backward, eventually almost touching the forehead. Alfred Russel Wallace remarks that "it is conceivable that these tusks were once useful, and were then worn down as fast as they grew, but that changed conditions of life have rendered them unnecessary, and they now develop into a monstrous form. . . ."

W. SUSCHITZKY

BABIRUSA (BABIRUSSA BABYRUSSA)

The babirusa is a docile, timid, night-hunting animal of the dense jungle. They root in soft soil near rivers and in swamps, the male usually going ahead while the mother and young follow, foraging on upturned tidbits of animal and plant matter. *See* also ARTIODACTYL.

BABISM (BABIISM), the religion founded by Mirza 'Ali Mohammed of Shiraz, who in 1844 declared himself to be the Bab (*q.v.*; Arabic "gate") through whom a renewed divine revelation should come. The title Bab originated with the Shi'ite sect of Muslims (*see* SHI'ISM), who believe that the spiritual authority of Mohammed at his death was transmitted to Ali (*q.v.*), his cousin and son-in-law, from whom it passed to his descendants, the 12 divinely chosen Imams (leaders) of the Shi'ite sect (*see* IMAM). The 12th and last Imam disappeared from human view *c.* A.D. 874 but the Shi'ites believe him still alive, though hidden. For a short time after disappearing, the Imam kept contact with his followers through agents, called by the title Bab, who acted as his spokesmen. By assuming the title, Mirza 'Ali Mohammed thus claimed to renew the broken communication with the occluded Imam.

Shi'ites also believe that at the end of time the 12th Imam (Imam Mahdi) will reappear to establish justice on earth. Abandoning the title Bab, Mirza 'Ali Mohammed soon proclaimed himself this expected Imam Mahdi. His followers consequently began to call him Qa'im, "He who shall arise," a traditional name for the coming Imam.

Still later he was called "His Holiness the Highest Point" and "His Holiness the Lord Most High." These two titles and other evidence show that he was looked upon as a divine figure in the fullest sense. Use of the term "Point" is explained by an alleged tradition from 'Ali that the meaning of the entire Koran is contained in its first chapter, the meaning of the chapter in the invocation, the meaning of the invocation in the first letter and the meaning of the whole in the dot or point that distinguishes that letter from others of similar form. In the "Point" is found the summation of all wisdom, the fullness of divine knowledge and power.

Babi doctrine holds that God in himself, in his essential divine nature, is unknowable, beyond the possibility of human comprehension. He is known, however, through a series of manifestations of himself, the great prophets who have appeared in the past. Among these manifestations the Babis list the Jewish prophets, Christ and Mohammed, and the Baha'is have added to the series the founders of other, non-Semitic religions (*see* BAHA'I FAITH). Each of the divine manifestations came with a teaching appropriate to the needs of those whom he addressed. When his teaching was no longer useful, a new manifestation appeared to further human spiritual enlightenment. Altogether this body of teachings evidences a divine plan for the continued and progressive spiritual education of man. Unlike the Muslims, the Babis do not believe in the end of prophecy but consider that it shall continue eternally for the duration of the universe itself. Denial of the finality of Mohammed's prophethood has brought them into serious conflict with Muslims in many countries. Babis also believe that each divine manifestation has foretold his successor. The Bab was prefigured in Jewish expectations of the Messiah, Christ's promise of the Comforter and Muslim teaching of the return of the Imam. The Bab also pointed to one who would come after him, his successor, "Him whom God should manifest." Baha'is have taken this prediction to refer to Baha'ullah (*q.v.*), but it is not certain that the Bab so intended.

One important Babi belief has to do with numbers and the equivalence of names in terms of numerical value. Each letter of the Arabic alphabet traditionally has a numerical value, and it is common in Muslim literature to find dates and numbers represented through the numerical values of words. For the Bab the number 19 was of particular significance since it was the "number of unity"; *i.e.*, the total of the values of the separate letters of the Arabic word for unity (*wahid*) when added together. The mystic significance of numbers was decisive in the Bab's appointment of his successor and the limitation of the number of his major disciples (there were 18 of these plus himself for a total of 19). The number 19 was also the basis of the system of reckoning time and the monetary system proposed by the Bab.

Most of the Bab's life after his "manifestation" (1844) was spent in prison. He was executed at Tabriz by government order in 1850. During his lifetime and after his followers were subjected to cruel persecutions that persist to the present day. The chief reasons for the opposition to the Bab and his religion were probably three: (1) the lightninglike spread of his new doctrines; (2) the offense to Muslim religious beliefs posed by his claims; and (3) the political implications of claiming the title Imam.

When the Bab died, his followers soon split into two sects. The Bab had nominated as his successor one Mirza Yahya, known as Subh-i-Azal (Dawn of Eternity). The group split when Baha'ullah (Subh-i-Azal's half-brother) publicly proclaimed himself "Him whom God should manifest," as foretold by the Bab. The majority of Babis soon accepted this claim as authentic and became Baha'is. Some, however, remained loyal to Subh-i-Azal, and strife resulted between the factions, causing the death of several persons. To prevent public disorder the Turkish authorities banished both Baha'ullah and Subh-i-Azal, to Palestine and Cyprus, respectively; conflict, nevertheless, continued between the two parties. There are today very few Babis, the Baha'is having become of vastly

greater importance. It is the latter whose world-wide organization and ethical teachings have saved the Bab from oblivion. *See* BAHA'I FAITH.

(C. J. A.)

BABITS, MIHÁLY (1883–1941), Hungarian poet, novelist and essay writer, who played an important part in the literary life of his country in the early 20th century, was born in Szekszárd on Nov. 26, 1883, of a middle-class family (his father was a judge). He read Hungarian and classics at the University of Budapest and then taught in various secondary schools. His first volume of poetry appeared in 1909. During World War I he had to resign from his teaching post because of his pacifism and thereafter devoted all his energies to literature. Babits belonged to the group of writers and poets which included also Endre Ady, Zsigmond Móricz and Dezső Kosztolányi, whose principal organ was *Nyugat*, one of the most important reviews in Hungarian literary history, of which he later became editor. A shy, reticent man, Babits found himself charged with responsibilities he had not sought. Thus, in 1929, he became the "curator" of the important Baumgarten prize, awarded annually to a writer "who had remained faithful to his principles." He died in Budapest, Aug. 4, 1941.

Babits is an intellectual poet, difficult to understand, imbued with the spirit of antiquity. His style is remarkable for its compression. Self-centred and withdrawn in his early period, he later left his "ivory tower," and turned to deal with the pains and problems of his fellows. He wrote several novels. In some such as *Halálfiai* ("The Children of Death"; 1927) he gave a poignant picture of the decaying middle classes. A prolific essay writer and a brilliant translator, he translated, among other works, the plays of Sophocles, Dante's *Divina Commedia*, medieval Latin hymns and works by Shakespeare and Goethe. (Ds. SR.)

BABOL (BABUL, formerly BARFURUSH), the chief town of a populous district in Mazanderan, the Second *ostan* (province) of Iran, lies on the eastern side of the Babol river about 15 mi. from the Caspian sea. The river is bridged there by the old highway built by Shah Abbas I to cross the Caspian provinces from east to west. Pop. (1956) 36,194. The town gained importance during the reign of Fath Ali Shah, although Abbas I had previously laid out a pleasure garden and summer palace there, the remains of which are known as Bagh-i-Shah. It is still a lively regional centre with large and crowded bazaars, well-built houses in burnt brick and tilted and tiled roofs, paved streets and handsome little mosques and funeral towers. There are some manufacturing activities but bigger developments have occurred at the nearby town of Shahi (pop. 23,055), a former village which profited greatly because of the Trans-Iranian railway joining the Mazanderan plain there.

Meshed-i-sar, now called Babol Sar, was formerly the port of Babol at the mouth of its river on the Caspian, but has completely lost its function since the level of the sea dropped about 6½ ft. leaving the riverside quays dry and the undredged sand bar impassable even for native lighters. However, Babol Sar developed into a fashionable seaside resort, frequented by well-to-do people from Teheran. It is reached through Babol by the main motor road and an airport has been constructed there. Its population was 7,237 in 1956. (H. Bo.)

BABOON. The early English naturalist John Ray (1627–1705) defined baboons as short-tailed quadrupedal monkeys, but no such natural group exists. Scientifically the term is restricted to five species constituting the genus *Papio* but in a wider sense includes two related stump-tailed species, the drill and mandrill. The name has also been applied to a stump-tailed monkey from Celebes (*Cynopithecus*) and certain other large macaques (*e.g.*, the pig-tailed *Macaca nemestrina*), and sometimes also to the gelada (*Theropithecus*); in Guiana it is colloquially applied to the red howler (*Alouatta seniculus*).

Typical baboons, as above restricted, are heavy-bodied terrestrial quadrupeds with large heads, large cheek pouches and long, truncated, naked muzzles with the nostrils at the tip. Their tails are carried in a characteristic arched manner. Because of their enormous canines and powerful limbs, they can be very destructive to crops and are dangerous adversaries, especially since they associate in large troops. Remarkable for their degree of social cohesion, the members of a troop are subservient to the whims of a dominant male leader who guards his harem and other adherents on the understanding that his personal dietetic and sexual demands receive prior consideration.

Baboons are confined to the drier savanna and rocky districts in Africa south of the Sahara and in Arabia, being rarely found in forest and then only marginally. Almost omnivorous, they favour roots, peanuts, fruit, insects, birds' eggs and even larger creatures, which they catch and tear apart by hand. They are noisy, emitting alarm notes resembling a dog's bark besides feebler calls; *e.g.*, grunts, squeals, chatterings, each with a definite meaning. Communication between individuals is also effected by posturings and tail signaling. They are highly intelligent and educable.

Coat colour varies considerably, but coat texture is always harsh. Over the shoulders in adult males, the coat tends to be lengthened, forming a cape; the underparts, hands, feet, face and buttocks are naked, and the last-mentioned site often is vividly coloured. Males greatly exceed the females in size. The latter, at the midpoint of the menstrual cycle, present an unsightly appearance because of the high degree of swelling around the genital region. Normally only one young is born at a time, gestation lasting seven months.

Of the known species the largest is the darkly coloured South African chacma (*P. ursinus*) and the smallest the bright rusty Guinea baboon (*P. papio*). The most spectacular is the sacred, or Arabian, baboon (*P. hamadryas*) of northeast Africa and Arabia, sacred to the ancient Egyptians and characterized by the enormously elongated hairs of the neck and shoulders of the adult males and the bright red naked sitting pads. Others are the olive baboon (*P. anubis*) ranging over west, central and eastern Africa and the long-limbed yellow baboon (*P. cynocephalus*) of Rhodesia. *See* PRIMATES: *Old World Monkeys* (*Catarrhines*): *Baboons and Mandrills*; CHACMA; DRILL; GELADA; MANDRILL.

BABRIUS, the author of a collection of verse fables written in Greek not later than the 3rd century A.D., was probably a Hellenized Roman, but nothing is known of his life. The fables are versions of Aesopic fables, with some additional stories, rendered into the scazon, or choliambic, metre. But the metre follows Roman rather than Greek practice, both in the use of resolved feet and in the attention paid to ictus and accent, above all at the end of the line. The fables were very popular in antiquity and originally comprised ten books. The extant collection is in two books, the second being incomplete. Many are beast fables, and almost all are short and simply written. But there is a definite satirical element which suggests urban sophistication, and there is often a pointed conclusion in the last two lines.

(G. B. Ko.)

BABUR (ZAHIR UD-DIN MOHAMMED) (1483–1530), first Mogul ruler in India, poet, diarist and military adventurer, was born on Feb. 14, 1483. A Barlas Turk, he was descended on the male side in the fifth generation from Timur (*q.v.*) and on the female side in the 15th degree from Genghis Khan (*q.v.*). In succeeding his father as ruler of Fergana (*q.v.*) in 1494, Babur inherited a share in the interminable family struggle among the descendants of Timur for the towns and fertile zones of Transoxiana, an area enriched by the caravan and entrepôt trade with China, India and Iraq. Important in the power struggle was an ability to attract an armed following and to draw revenue from

herdsmen, cultivators, artisans and traders. The weapons were adroitness in managing the allegiances and antagonisms of an unruly but not uncouth military elite, united or divided by close family ties, and personal address and ability to inspire affection among men unsusceptible to the appeal of more impersonal loyalties of language, race or state. The young Babur owed his survival and his success in the political tournament to his winning personal qualities and the swift opportunism that drew him later to conquer the plains of northern India.

From 1494 to 1504 Babur struggled to retain Fergana and to establish himself at Samarkand, Timur's old capital, in face of more powerful Mogul relatives and Shaibani Khan, ruler of the Uzbek tribes to the northeast of the Jaxartes (Syr Darya) river. Brief occupations of the city in 1497 and 1501 were followed by a decisive defeat by Shaibani Khan at Sar-i-pul in April–May 1501 which left Babur bereft of both Samarkand and his own principality. Seeking a headquarters beyond Uzbek power, in 1504 he settled at Kabul and shortly after the failure in 1511–12 of a last attempt to re-establish himself in central Asia and Samarkand he turned to exploiting the political possibilities to the east and south of Kabul. After probing raids toward India and the occupation of Kandahar in 1522 Babur was invited by Daulat Khan Lodi of Lahore and 'Alam Khan, an uncle of Ibrahim Lodi, the sultan of Delhi, to help them against Ibrahim. Northern India, divided among the largely autonomous and quarreling Afghan chiefs under the weak suzerainty of Delhi and the Rajputs under the paramountcy of Rana Sanga of Mewar, was in no state to resist him. In April 1526 Babur defeated and killed Ibrahim Lodi at Panipat and occupied Delhi and Agra. In March 1527 he defeated Rana Sanga at Khanua and in May 1529, at the battle of the Gogra, near Patna, he overthrew the Afghan chiefs settled in Bihar and Bengal. When he died, however, at Agra on Dec. 26, 1530, Babur had only succeeded in staking a military claim to empire in India, a claim which was to be consolidated by his grandson Akbar (*q.v.*).

BIBLIOGRAPHY.—Babur's frank and engaging memoirs, the *Baburnama*, have been translated from the Turki by A. S. Beveridge, 2 vol. (1921–22). *See* also L. F. Rushbrook Williams, *An Empire Builder of the Sixteenth Century* (1918); F. Grenard, *Baber* (1930); *Cambridge History of India*, vol. iv, *The Mughul Period* (1937). (P. H.)

BABUREN, DIRK (THEODOR or DIRCK) **VAN** (*c.* 1590–*c.* 1624), Dutch painter, was born at Utrecht in about 1590 and died apparently soon after 1623, the latest date on any known work. Baburen was a pupil of Paulus Moreelse and worked in Rome from 1617–20. Like other painters of the Utrecht school, such as Gerard van Honthorst and H. Terbrugghen, with whom his art has much in common, he was profoundly influenced by the powerful and dramatic chiaroscuro style of Caravaggio. His own manner is broad and forceful, but compared with the greater Caravaggesque masters betrays a certain coarseness in conception and weakness in draftsmanship and modeling. All his known works are figure compositions, and these include, besides a number of religious subjects, genre pieces of the Utrecht school type, with half-length, life-size figures. Among notable pictures are the "Entombment" in the church of S. Pietro in Montorio, Rome; "Christ Among the Doctors" in the National gallery, Oslo; and the "Procuress" in the Museum of Fine Arts, Boston.

(R. E. W. J.)

BABY BLUE-EYES (*Nemophila menziesii*), a small North American plant of the waterleaf family, Hydrophyllaceae, a popular wild flower of California, native to moist places in valleys and mountains. It is a low, usually diffuse, annual, with stems about six inches long and minutely hairy divided leaves. The bell-shaped light-to-deep-blue flowers, one-half inch to one and one-half inches across, often veined with purple and dotted toward the centre, are borne in one-sided clusters. It is cultivated as an annual; seeds should be sown one-fourth inch deep in any ordinary garden soil, in full sunlight, as soon as warm weather is assured. Thinned out to three to six inch intervals, they will bloom from July to frost. *See* NEMOPHILA. (N. TR.)

BABYLON, one of the most famous cities of antiquity, is situated on a branch of the Euphrates river just north of the modern town of Hillah in southern Iraq. At this latitude there is only a narrow strip of land between the Euphrates and the Tigris, and the city thus stood at a nodal point that enabled it to intercept traffic between Syria and the Persian gulf on the one hand, and between the two rivers on the other. In the first half of the 18th century B.C., under Hammurabi (*q.v.*), who overcame Rim-Sin of Larsa, Babylon succeeded to suzerainty over the great part of Mesopotamia. (*See* BABYLONIA AND ASSYRIA.)

It was, however, as a religious centre that the city attracted both power and prestige, and from the time of Hammurabi onward an established priesthood fostered the cult of Marduk there. Even the kings of Assyria found it politic to receive what was practically a coronation rite in Babylon. The priests did not fail to take advantage of the murder of Sennacherib (*q.v.*) and to proclaim that this misfortune was due to the failure of that prince to submit to Marduk. As S. Langdon showed, it is significant that there was "consistent reference to the great temple of Marduk on the very bricks employed in the reconstruction of older and far more famous sanctuaries throughout Babylonia."

Old Babylon, the capital of Hammurabi and his successors, was sacked as the result of a Hittite raid at the beginning of the 16th century B.C., but the statue of Marduk that was removed was restored to it by the Kassite king Agum II, *c.* 1570 B.C., after an absence of 24 years. Thereafter Babylon's career was checkered, although more than one monarch between that time and the 8th century B.C. endeavoured to impart to it something of its former glory. The city again suffered in the wars with Assyria, particularly at the time when the Chaldean soldier of fortune Merodach-baladan established his throne there. Sargon II (722–705 B.C.) recorded in a prism discovered at Nimrud that he found it wasted and ruined, a jungle infested with jackals. His attempt to rebuild the city was frustrated by the Aramaean tribes, and Sennacherib consequently leveled it to the ground in 689 B.C. Esarhaddon built a new town on the same site, but after his death one of his sons, Shamash-shum-ukin, who succeeded to Babylonia, revolted against Assyria. Babylon suffered the horrors of a siege and was eventually captured by Ashurbanipal (648 B.C.).

During the decline and fall of the Assyrian empire Babylon was ruled by an independent line of kings. In the late 7th and early 6th centuries B.C. Nabopolassar and his son Nebuchadrezzar rebuilt the city whose remains have survived until today; and it was at this time that Babylon attained its greatest fame. Nabonidus (*q.v.*), a heretic, the last of the Neo-Babylonian kings, earned unpopularity with the priests of Marduk and was succeeded by the Persian king Cyrus, who in 539 B.C. was allowed to invest Babylon without resistance. Under Cyrus' successors Darius I and Xerxes I, however, the city was plundered and punished for revolting against Achaemenid rule, and its defenses were demolished. Alexander the Great, who died in the palace of Nebuchadrezzar in 323 B.C., had intended to rebuild the ziggurat, but his successors established a new capital in Seleucia. Nonetheless the city was not deserted, as the remains of a Greek theatre testify, and as late as the Parthian period a school of learned astronomers flourished within it.

Topography, Buildings and Antiquities.—In spite of the statements of classical writers and the work of German excavators the topography of Babylon is far from clear. The earliest Greek writer on the city is Herodotus, who describes the town as standing on a broad plain and forming an exact square, with a total circuit of about 60 mi. Other Greek writers, Ctesias, Strabo and Cleitarchus, give a different estimate amounting to about 42 mi. Various attempts have been made to correlate these statements with the remains that can be observed, for the actual walls of the city have an extent of only about 11 mi. It has been suggested that Herodotus included the towns of Borsippa, Kish and Sippar within his total circuit. In fact, however, these discrepancies, which are due to hearsay and to imperfect observation in ancient times and to incomplete geographical and archaeological surveys in modern, remain unresolved. Changes in the course of the river and the destruction wrought by medieval and modern canals as well as

the rise in the level of the water table have obliterated the evidence or so effectively concealed it as to make it practically impossible to reconstitute the ancient circuit. Since the earliest times the Euphrates has frequently shifted its course, and though the greater part of the city down to the Neo-Babylonian period lay on its eastern bank, during the Persian and Greek periods an arm of the river had, according to R. Koldewey (*see* Bibliography, below), shifted to the east of the citadel. Transverse canals with sluice gates ran in an east-west direction north and south of the citadel; the burnt-brick piers of a Neo-Babylonian bridge that spanned the Euphrates provide important evidence of the hydrography.

Herodotus' defective account of the temples and the town walls and his unverifiable measurements have led many authorities to doubt if he ever visited the site, but one of his remarks about the ziggurat, popularly known as the "tower of Babel," bears the authentic imprint of an eyewitness: "when one is about half-way up, one finds a resting-place and seats, where persons are wont to sit some time on their way to the summit" (Herodotus i, 181; Eng. trans. by G. Rawlinson revised by A. W. Lawrence, 1935). Any traveler, ancient or modern, would have found it beyond his powers to describe this complex site without making a prolonged stay. It seems reasonable to conclude that Herodotus made a brief halt in the course of a caravan journey, that he listened to the tales of garrulous guides and perhaps filled out his notes from some earlier author. His understanding that the town was laid out on a rectangular grid is approximately correct, and his references to moat, ditch, embankment and towers, streets and houses, while unsatisfactory in detail, have more than a touch of verisimilitude.

What in fact is known about the topography, buildings and antiquities of Babylon is mainly due to the work of R. Koldewey, who conducted excavations there on behalf of the Deutsche-Orient Gesellschaft between 1899 and 1917. There were double inner and outer walls on the left bank of the river, composed of sun-dried and burnt brick, reinforced with towers at intervals and further strengthened by an escarpment and fosse. The outer double walls reached a maximum of 7.1 m. in width.

The most impressive monument on the site is the great Ishtar gate, an enormous burnt-brick structure more than 12 m. high, decorated with brick reliefs, in tiers, of dragons (the *shirrush*) and young bulls. The gate was a double one, and on its south side there was a vast antechamber. Through the gate ran the famous stone- and brick-paved procession street that has been traced over a length of more than half a mile. The sides of the streets were decorated with brick lions *passant*. It has been estimated that there were 120 lions along the street and 575 dragons and bulls, in 13 rows, on the gate. Not all of these reliefs were visible at the same time, however, for the level of the street was raised more than once and even originally the lowest rows, which were irregularly laid, may have been treated as foundation deposits. The Iraq antiquities department has reconstructed this thoroughfare at one of the higher levels. The upper courses of the friezes were composed of polychrome glazed bricks; stylized floral designs on the top give a brilliant final touch to this spectacular façade. The procession street, which entered the city from its northern side, flanked the great palace area and the sacred enclosure or ziggurat, known as Etemenanki, where it turned west and led up to a bridge across the Euphrates. Not far to the south of this section of the road was Esangila, the principal temple of Marduk, patron god of the city.

West of the procession street and southwest of the Ishtar gate lay the palace area, which covered more than 13 ac. of ground and where the pomp and majesty of Babylon were concentrated. There were five blocks of annexed buildings, each of which centred around a vast courtyard. The central block contained a throne room measuring 60 by 55 m. and decorated with blue glazed bricks, some of which were incorporated in columns surmounted by double capitals of Ionic type with half rosettes and palmettes. The roofing of this great chamber presents a technical problem; it may have been achieved by means of overlapping beams laid diagonally from the corners of the room, a device known to the Parthians later on. Hundreds of smaller rooms within this area housed the royal family and court officials and must have served for the storage of royal treasure as well as for transacting business. This vast throne room can be associated with the scene of Belshazzar's feast and the writing on the wall, which foretold the doom of Babylon at the hands of the Medes and the Persians (Dan. v; the statement in verse 2 that Nebuchadrezzar was Belshazzar's father has to be emended in the light of the cuneiform records, which state that Belshazzar was in fact the son of Nabonidus, the last king of Babylon). On the other hand the tradition that associates the series of magazines in the northeast corner of the palace area as the site of the "hanging gardens" can be dismissed as fiction. From tablets discovered therein it is now known that this was the place where Jehoiachin, king of Judah, was held in captivity by Nebuchadrezzar in 597 B.C. together with his court and craftsmen and smiths, among whom there were Philistines, Phoenicians, Elamites, Medes and Persians, Egyptians and Ionian carpenters. The whole of this palace area or *Qasr* as it is now locally known was strongly defended: on the west by an enormous bastion (*halsu rabitu*) on the river bank; on the north by a huge buttressed wall, *Imgur Bel*; and on the south side by a canal, as well as by powerful buttresses, which also flanked the eastern wall. While traces of the handiwork of Assyrian monarchs, notably Esarhaddon, have been found, it is to Nebuchadrezzar (605–562 B.C.) that credit must be given for the greatest architectural achievements out of the many Neo-Babylonian monarchs who had a hand in the embellishment of the city during the last century of its lifetime.

STONE BAS-RELIEF FROM THE ESANGILA, SHOWING ASHURBANIPAL CARRYING BASKET IN THE REBUILDING OF THE TEMPLE

Many well-built and spacious temples were found in the course of the excavations, including those of Ninmah, Marduk (the Esangila), Ninurta and Ishtar of Agade, but a fraction of the total named in the records. Every temple had an oblong cella with podium for the god's statue against the middle of the long wall at the far end of the sanctuary, opposite the door; the other rooms were grouped around a square or oblong courtyard. Spacious houses, notably the "great house" of Merkes, were characterized by a sawtoothed façade repeated in various buildings at Ur. The ziggurat or staged temple tower known as Etemenanki had a special *temenos* or walled enclosure that ensured its privacy. It was dismantled by Alexander the Great, who died before he could rebuild it: his successors the Seleucids erected a Greek theatre.

After the conquest of Babylon by Cyrus the Persians took over the capital, which for a time prospered, as is known from many Achaemenid economic documents. A hypostyle building (*apadanna*), including a black limestone plinth inscribed with the name of Darius I and ornamented glazed brickwork, may be contemporary. His successor Xerxes I destroyed the statue of Marduk as punishment for a nationalist uprising. Large numbers of small artifacts as well as some sculpture were found, notably a basalt monument known as the "Lion of Babylon," which depicts a man supine under the beast's belly, a traditional formula for illustrating the king's triumph. There are now reasons for assigning this to the Neo-Babylonian period.

With the death of Alexander the Great, Babylon, although still a religious centre, ceased to have any political significance, for the new capital of Mesopotamia was transferred by his successors to Seleucia on the Tigris. A large part of the old city buried under a deep bed of silt remains to be found, and the Babylon of Hammurabi, of which only the slenderest traces have been detected, now lies beneath the water table.

BABYLONIA AND ASSYRIA, the two ancient kingdoms of Mesopotamia (*q.v.*) or modern Iraq. Of these, Babylonia roughly corresponds to the southern plain between Baghdad and the Persian gulf, while Assyria is the northern region around present-day Mosul. Their names are derived from those of their capitals, Babylon and Ashur, respectively. A high civilization was developed in Babylonia around 3000 B.C., and Babylonia remained the cultural centre of the region until the Persian conquest in 539 B.C. Political power, however, shifted back and forth between Babylonia and Assyria. Although recorded history begins in Assyria about one millennium later than in Babylonia, the Assyrians became the leading power, especially between 900 and 600 B.C., owing to their military and administrative skills.

Babylonia and Assyria shared a common Semitic language called Assyro-Babylonian or Akkadian. In Babylonia this language superseded that of an earlier population, Sumerian, and it was the Sumerian people that first developed the high civilization of Babylonia.

Until the 19th century the knowledge of Babylonia and Assyria was based on the Old Testament and a few Greek writers. Not until after the discovery of ancient monuments and written documents in the two countries, and especially after the decipherment of the cuneiform script and the languages written in this script, did the history and civilization of Babylonia and Assyria become known. Covering, as it does, three millenniums, this civilization underwent many changes, although it retained certain main characteristics. The sources are unevenly distributed over this long time span, being abundant for some periods but scarce or entirely lacking for others. Therefore there remain gaps in our knowledge of the political history as well as of the development of institutions, social structure, religion, art and literature, as will be shown below. (H. G. Gk.)

This article is organized as follows:

I. GEOGRAPHY

While the political boundaries of Babylonia and Assyria varied greatly from period to period, these two countries are customarily considered to comprise all the lands situated between the Tigris and Euphrates rivers, as well as the long stretch of land extending from the Tigris eastward toward the Iranian plateau. In modern usage this area is often called Mesopotamia, a term used by ancient Greek historians and geographers. It corresponds roughly to the region enclosed within the political boundaries of the present-day state of Iraq. Divided by a line drawn between the two rivers where they come closest to each other (near the modern city of Baghdad), two areas are distinguished: the southern area, identified with Babylonia, and the northern area, identified with Assyria.

1. Physical Geography.—The southern area is formed mainly by the alluvial deposits of the Tigris (Sumerian Idigna; Akkadian Idiglat), the Euphrates (Sum. Puranun; Akk. Purattu) and the many canals between. In its central part there is a slight elevation, called Edin in ancient times, while the southern part, close to the Persian gulf, extends into a full marshland. The main rivers are the Diyala (ancient Turnat), the Kerkha (anc. Uqnu) and the Qarun (anc. Ulay), all left-bank tributaries of the Tigris. In two important respects the ancient courses of the Tigris and Euphrates differed greatly from those followed by these rivers in modern times: in ancient times, the main course of the Tigris ran southward from Kut, following the course of the modern Shatt al Hay; and the course of the Euphrates ran past the ancient Babylon along a line 15–30 mi. E. of the present course of the river.

The higher-lying northern area consists of a plateau broken up by the ridges of Karaja Dag (anc. Izala), Tur 'Abdin (anc. Kasiyari) and Sinjar (anc. Singara), and the rivers Khabur (anc. Haburu), Balikh (anc. Balihu) and the largely dry Wadi Tartar

(anc. Tartara), all situated between the Tigris and the Euphrates. The main mountain chain east of the Tigris is Jabal Hamrin (anc. Epih), and the main rivers there are the Great and Little Zab (anc. Zabu) and the 'Adem (anc. Radanu).

2. Babylonia.—Originally the name of the provincial city of Babylon (anc. Babili, misinterpreted in ancient times as Bab-ili, "the Gate of Gods"), the name of the country of Babylonia begins to appear in the Old Babylonian period, when the rulers of Babylon, especially the great conqueror and lawgiver Hammurabi, succeeded in uniting the southern half of the Land of the Two Rivers. Politically, Babylonia extended in that period northward along the Tigris toward Ashur, and along the Euphrates toward Mari. Babylonia reached its highest political expansion in the Neo-Babylonian period when its conquered territories included all of Mesopotamia, Syria and Palestine. Babylonia proper was known also under the term "Kardunias," introduced in the Middle Babylonian period, and "Kaldu," "the land of the Chaldeans," known in the Neo-Babylonian period.

The main cities of Babylonia, from south to north, are: Eridu (modern Abu Shahrain), Ur(im) (mod. Tell el Muqayyar), Larsa(m) (mod. Tell Sankarah), Erech or Uruk (mod. Warka), Lagash-Girsu (mod. area of Telloh), Umma (mod. Jokhah), Shuruppak (mod. Tell Fa'rah) and Adab (mod. Bismayah), in the southern part; Nippur (mod. Nuffar), Marad (mod. Wannat Sa'dun) and Isin (mod. Bahriyyat), in the central part; Borsippa or Barsipa (mod. Birs Nimrud), Babylon (mod. Hillah), Kish (mod. Uhaymir), Cuthah, Kutua, Kutha or Kutu (mod. Tell Ibrahim), Sippar (mod. Abu Habbah) and Upi-Akshak (unlocated), in the northern part. East of the Tigris are situated Eshnunna or Ishnun (mod. Tell Asmar), Tutub (mod. Khafajah) and Der (mod. Badrah).

3. Assyria.—The name of the country of Assyria, derived from the name of the city of Ashur (Ashshur), originally designated a stretch of land situated between the Tigris river and the mountains of Iran. In its further expansion Assyria included all the lands situated between the Tigris and the Euphrates, called Hanigalbat in ancient times. The Assyrian empire reached its greatest expansion in the New Assyrian period with the conquest of Mesopotamia, Syria, Cyprus, Palestine and Egypt and of large areas in Iran, Armenia and Anatolia.

The main cities of Assyria, outside Ashur (mod. Qal'at Sharqat), the most ancient capital of Assyria, are: Nineveh or Ninua (mod. Quyunjiq), the later capital Kalakh or Kalhu (mod. Nimrud), Arba'ilu (mod. Irbil), Kakzu (mod. Sadawah) and Arrapkha (mod. Kirkuk), all situated east of the Tigris; and Mari (mod. Tell el Hariri), Harran (mod. Harran) and Nasibina (mod. Nesibin), situated between the Tigris and the Euphrates.

(I. J. G.)

II. ARCHAEOLOGY, ARCHITECTURE AND ART

The term "Babylonia and Assyria" is here used synonymously with "Mesopotamia." The area under consideration is not determined by the political boundaries of the kingdoms of Babylonia and Assyria, and periods much earlier than those that witnessed the appearance of Babylonia and Assyria as political entities are covered.

A summary of the history of Mesopotamian archaeology, its division into periods and the methods of establishing relative and absolute chronology are given elsewhere (*see* ARCHAEOLOGY: *Egypt and Western Asia*). This article surveys the material that has accumulated as a result of over a century of archaeological activities in Mesopotamia. The wealth of this material is such that it is very difficult to do it justice in a relatively short article. Some aspects of Mesopotamian archaeology are consequently omitted, while the neighbouring regions of Elam, to the east, and Mari, to the northwest, are mentioned only exceptionally.

A. ARCHITECTURE

1. Prehistoric Periods.—The earliest manifestations of architecture in Mesopotamia probably remain unknown. At Jarmo (*q.v.*), the earliest village known, the several layers of houses excavated have thin walls made of packed mud and, occasionally, stone foundations. The buildings consisted of agglomerations of rather small quadrangular rooms, with no apparent principle guiding their arrangement. Since few doorways were found it is difficult to recognize individual houses. Considering the very small area excavated, the seeming lack of planning does not preclude the existence of structures of a more orderly plan in this village or on contemporary sites yet unknown. At the somewhat later sites of Hassuna and Matarrah, where larger areas were excavated, fairly well-planned buildings were found alongside a jumble of rooms not greatly different from those at Jarmo. Of special interest are two: one house in Hassuna and another at Matarrah. Both seem to be organized on the same principle, namely that of a central room or court flanked by smaller rooms. These represent modest rudiments of the tripartite plan that finds monumental expression in much larger buildings of later periods.

Of the next, Tell Halaf, period fairly substantial and regular buildings consisting of quadrangular rooms are known. There are also round structures, of which the tholoi at Arpachiyah are the best examples.

Buildings possessing features that characterize temples throughout many later periods were found in the lower levels at Tepe Gawra. Though they are poorly preserved, the plan is clearly tripartite, with a relatively large oblong central room or court flanked more or less symmetrically on two sides by smaller rooms. The central room contained such structures as a small "offering table" and an altar or podium, which regularly occur in later temples. In addition to quadrangular buildings, round houses were found at Tepe Gawra in an early Ubaid period stratum.

Alongside such structures, whether secular or religious, occur a number of less articulate plans. Indeed, at no time is a single type of plan of house, temple or palace used exclusively. The earliest large architecture at Tepe Gawra is represented by stone foundations of a large structure assigned to stratum XIV. Though it differs in plan from identified temples, the possibility that it was a temple cannot be excluded, but it may have been an exceptionally large house or palace.

A group of three temples of monumental character was discovered in stratum XIII of the Ubaid period at Tepe Gawra, but the plan of only one was well preserved. Its façade faced an open space to the southeast and consisted of a large central double niche flanked by two symmetrical projections. The walls were elaborately decorated with buttresses and recesses, a feature that survived in Mesopotamian temple architecture for more than 3,000 years. The entrance was not through the central niche but between two double buttresses to the left of it. Within the temple were two parallel walls (about four metres apart) that did not run the whole length of the building but allowed wide openings on either end. They too were decorated with double buttresses. The centre of the northeast wall was the focal point of the temple. The plan of this temple clearly manifests the peculiarly early Mesopotamian (Sumerian?) bent-axis approach to the focal point of a temple.

The series of temples of the Ubaid period discovered at Eridu beneath the great ziggurat show unmistakable affinities with the temples of the north. The tripartite scheme and the elaborate decoration with recesses and buttresses are present.

2. Protoliterate and Early Dynastic Periods.—The tripartite temple plan found monumental expression in the Protoliterate period. Several such temples, some built on a truly monumental scale, were discovered at Warka (Uruk; biblical Erech). They were erected at ground level or on a low socle, but the so-called White temple, of which several rebuildings could be traced, was built on a high platform and approached through a series of stairways or ramps. A very similar temple built on a platform subsequently was discovered at 'Uqair.

The temples of the Early Dynastic (E.D.) period generally were built according to plans different from those common in earlier periods. The successive rebuildings of a relatively small temple, dedicated to the moon-god Sin, at Khafajah, provide the only known example of a gradual transition from a tripartite to a typically Early Dynastic plan. In such temples, in contrast to

the earlier ones, the cult chamber is located not in the centre but at the end of the building complex. It is approached through a single main entrance by way of a series of rooms or courts. This plan resembles more that of a dwelling, and the outside presents a less monumental appearance. Although the temples of the Early Dynastic period vary considerably, they all have the same type of cult chamber. This is an oblong room containing such features as an offering table, a hearth and, nearly always, a structure against one of the short walls, usually called an altar. Indeed, some temples consist only of such a room decorated with buttresses on the outside and with an entrance through one of its long walls. Occasionally there is more than one cult room in a temple. Sometimes the "altar," which was the focal point of the sanctum, was placed in front of a shallow niche. Occasionally it was separated from the rest of the sanctum either by two piers projecting from the longer walls or by a series of low rectangular columns with rounded tops. It has been suggested that this separation led to the development of the wide inner sanctum of later periods.

There also appeared in the Early Dynastic period a type of temple in which the sanctuary and its ancillary architectural elements were contained in a large enclosure. The one most thoroughly investigated and recorded is the Temple Oval at Khafajah. Its double enclosure contained a high platform upon which the sanctuary stood.

A relatively small number of private houses of the Early Dynastic period are known, most of them from Khafajah. It is difficult to recognize a definite architectural type for the Early Dynastic I phase. While some rooms are large enough to have been open courts, the arrangement of smaller rooms in relation to them does not follow any clear pattern. Such houses often have more than one entrance.

In the Early Dynastic II phase the houses at Khafajah were larger, their walls were thicker, and a distinctive plan that survived into much later times appeared. This type of house is planned around a sizable central court. The number of rooms varies. Now and throughout later Mesopotamian history there is but a single entrance from the outside. Usually the central court is reached through an antechamber, often flanked by a second room. The other rooms are reached through the court. There is usually one room, larger than the others, which probably was the "reception room" or "master's room." Such features as ovens, storage bins, drains, grinding stones and storage jars occasionally suggest the functions of different rooms.

A large building excavated at Kish and dated to the last phase of the Early Dynastic period was apparently a palace. It had an elaborate entrance, with external buttresses developed into projecting towers, and a colonnade that apparently supported the roof of a portico. An Early Dynastic building at Eridu that is very similar in plan consisted of two almost identical units, which suggests a twin palace. A much simpler Early Dynastic III "palace" (probably a "women's house") was found at Tell Asmar (ancient Eshnunna). It was rebuilt on a larger scale in the Protoimperial period, when it contained a large number of ablution places and toilets, all connected to a vaulted sewer under the adjoining street.

3. Historical Periods.—A fairly large area at Tell Asmar, excavated throughout a number of building levels, proved that plans of private dwellings did not change radically from the Early Dynastic through the Protoimperial and into the Akkadian period. Indeed, it is possible to follow the history of a single fairly large house throughout these periods and learn how it was modified, contracted or enlarged while still retaining its major features. The building material, however, did change. While at the end of the Early Dynastic period normal plano-convex bricks were still in use, during the Protoimperial period the plano-convex bricks became nearly flat but retained their oblong proportions. In the Akkadian period flat bricks were used almost exclusively and, though the oblong shape continued in use, square or nearly square bricks became predominant.

The few public buildings that are dated to the Akkadian period (for instance, the temples at Nuzi) closely follow Early Dynastic types. During the rule of the Guti apparently no monumental architecture was undertaken in areas under their domination. At almost the same time Lagash, under Gudea, had a period of great architectural and cultural achievement.

With the advent of the 3rd dynasty of Ur a great expansion of architectural activity took place all over southern Mesopotamia. The founder of this dynasty—Ur-Nammu—was one of the most active builders in Mesopotamian history, and his temples and temple towers (ziggurats) survive on several major sites. Vassal rulers of lesser kingdoms shared in this architectural activity. At Tell Asmar a temple dedicated to Shu-Sin (formerly read Gimil-Sin), a deified king of that dynasty, though relatively small, is one of the clearest examples of a new temple plan that thereafter became the predominant type in Babylonia. An axial approach from the entrance through an antechamber leads into a square court and thence to a broad cella with the focal point in the form of a niche containing the "altar" still on the same axis. A single series of rooms, all of about the same width, surrounds the court.

The outstanding architectural monuments of the Ur III period are undoubtedly the ziggurats or temple towers, the best preserved of which is the ziggurat at Ur. It measured 190 by 130 ft. at the base, and its outer face was decorated with shallow buttresses. The building consisted of a solid mass of sun-dried bricks alternating with layers of matting inserted to strengthen the cohesion between the bricks while the mortar was still wet. The outer surface was protected with a revetment of kiln-baked bricks. On the northeast side three stairways gave access to the first stage. Two of these were built against the structure while the third was perpendicular to it. Apparently a gatehouse existed where the three stairways met at the first stage. The central stairway continued to the top of the second stage. From the incline of the stairway it has been calculated that the second stage was about 17 ft. above the first. It is generally assumed that a third stage originally existed and that a shrine of some sort stood upon it.

Of the Isin-Larsa period, which followed that of Ur III, relatively few original architectural monuments are known. A number of houses at Ur show close affinities with earlier houses, going back to the Early Dynastic and Akkadian periods. One feature of the Isin-Larsa period is a strongly fortified, relatively small town area that may be called a citadel. One such citadel was found on Mound D at Khafajah (ancient Tutub) and a second at Tell Harmal only a few miles away, across the Diyala river. The existence of such strongly fortified citadels may reflect the military threat created by the advent of the 1st dynasty of Babylon, for apparently neither of the two survived into the Old Babylonian period.

The building activities of the 1st dynasty of Babylon, in contrast to those of the 3rd dynasty of Ur, appear rather insignificant. Apparently the rulers were now mainly concerned with the pious upkeep of earlier monuments, especially the temples and the ziggurats.

Excavations at Dur-Kurigalzu revealed some important buildings of the Kassite period. A contemporary temple at Warka shows a plan greatly different from traditional temple plans in both the south and the north. It may go back to an architectural tradition represented by temples found in strata IX–VIII at Tepe Gawra.

With the emergence of Ashur as the capital city of Assyria in the middle of the 14th century B.C., great building activity began. In the course of time a large number of temples dedicated to various deities were erected, some with ziggurats attached. At Ashur, too, was found a double temple with a double ziggurat.

In the New Assyrian period, in the first half of the 1st millennium B.C., great architectural monuments were erected not only in Ashur but also in Nineveh, Nimrud (ancient Kalakh) and Khorsabad (ancient Dur-Sharrukin). The last, built by Sargon II, is of special interest as a planned town unhindered by considerations of space or the presence of earlier ruins. The town was a near square, its corners oriented to the cardinal points of the compass, surrounded by a thick fortification wall with seven forti-

fied gateways. It covered an area of about 740 ac. Two palaces were placed astride the northwestern and southwestern walls respectively. The first was the main palace, built on an artificial platform about 45 ft. high and covering an area of about 25 ac. In front of it a strongly fortified citadel extended into the town. This palace was planned not only as the king's residence but also as an administrative and religious centre. Within its confines were a number of temples and a ziggurat. Architecturally the palace consists of a large number of units, each planned for its specific function, its rooms usually grouped around a court. The two largest courts cover areas of about 1.7 and 2.2 ac. respectively and may be considered "squares" rather than courts. The other palace is not fully excavated, and its function remains obscure. The new capital was never fully occupied and parts of the main palace seem never to have been finished. On the death of Sargon II, his son and successor Sennacherib returned to Ashur and then to the old capital of Nineveh.

With the fall of Assyria and the transfer of central power once more to the south during the Neo-Babylonian period, architectural activity was renewed in the south. Outstanding are the monuments found in the capital—Babylon—where tremendous fortification walls, numerous temples and palaces and a large ziggurat were erected. The temples on the whole differed from those in the north, maintaining the tradition established in the south as early as the 3rd dynasty of Ur. The palaces, like those in Assyria, consisted of an agglomeration of units within the confines of retaining walls. Kiln-fired bricks were used on an unprecedented scale, and molded glazed bricks, known also in Assyria, covered huge areas of exterior walls and decorated monumental gateways. The rather limited decorative motifs consisted of lions, bulls and monsters, often bordered with floral and geometric patterns. (*See* also BABYLON; PRE-HELLENIC ARCHITECTURE.)

B. ART AND ART OBJECTS

1. Sculpture.—Numerous human and animal figurines, modeled in clay, were found at Jarmo, and though hardly deserving to be called sculpture in comparison with later achievements in Mesopotamian art, some of these are very well shaped. Various species of animals are clearly recognizable. The great majority of the human figurines represent very markedly steatopygous nude females. In some the facial features as well as the arms, hands and legs are indicated; others consist only of the lower part of the body and the legs. They are nearly always represented in a seated or squatting position. This type of female figurine is found also in the somewhat later Hassuna and Halaf cultures. During the Ubaiḍ period a different type of human figurine appears, representing a standing nude female of rather slender proportions. The heads are well molded but in most cases look reptilian rather than human; there is no doubt that this was the modeler's intent. Sometimes the figure is depicted as holding and nursing a child, and some scholars identify it as the "mother goddess," while others see in it the female demon Lamashtu, the abductor of children. Clay figurines continued to be made throughout Mesopotamian history.

From prehistoric times there also survive miniature stone pendants and amulets, the excellence of workmanship of which is an evidence of the high degree of the stonecutters' skill, also manifest in contemporary glyptic.

The earliest examples of true sculpture in the round come from the Protoliterate period, outstanding among them being a magnificent though incomplete head from Warka, which may be male rather than female. Missing are the back part, the inlaid eyes and eyebrows and the hair. A lesser piece from the Protoliterate period is a stone statuette from the Sin temple at Khafajah.

No sculpture in the round is known from Early Dynastic I, but large numbers of stone statuettes date from E.D. II and E.D. III. The majority are from southern Mesopotamia, though some were found to the north, at Ashur on the Tigris and Mari on the Euphrates. These statuettes, representing both men and women, vary from a few inches to about three feet in height. Most of them are standing, but seated figures are not uncommon. They exhibit a great variety of dress and, in the female statuettes, coiffure. Though they show a great range of the sculptor's skill and of style, nearly all of them have one common feature: the arms are folded and the hands clasped in front of the body in an attitude of reverence. Sometimes the hands hold a cup and sometimes, especially in the seated figures, one hand holds a branch. The attitude of worship and the fact that nearly all the statuettes were found in temples leave no doubt that they represent the devout in the presence of the deity, as explicitly confirmed in later times by inscriptions carved on statues. The fact that an image could represent the worshiper may explain the surprisingly small dimensions of some of the sanctuaries, which apparently were intended neither for a congregation of worshipers nor for the performance of elaborate rites but rather as a depository where the worshiper, represented by the statuette, was forever in the presence of the deity. This function of the statuettes suggests that the deity as well as the worshiper was present in the cult chamber. A terra-cotta painted relief from the Ishtar temple at Ashur and two statues (male and female) from the Abu temple at Tell Asmar may represent deities. The Tell Asmar statues are in the worshiper's attitude, with hands in front of the body and holding a cup. They are larger than any of the statuettes found with them and have uniquely enormous eyes. They also have unusually carved bases, showing the emblem of the god of vegetation. Two distinct styles of Early Dynastic sculpture are recognized: in one the human features and body are stylized to form geometric planes and shapes; in the other the body and features are more naturalistic.

In the Akkadian period sculpture in the round, as well as other art forms, both continues earlier tradition and introduces a distinctive new style. A turbaned head from Adab and a magnificent copper head from Nineveh demonstrate the contrast in style with Early Dynastic sculptures, as represented by, for example, the figures of a god and a priest from Tell Asmar.

Numerous statues of Gudea and of his successors are known from Lagash. Some are carved of diorite, a hard stone that requires special skill in working and that had to be imported from distant sources. The traditional gesture of reverence, the clasped hands, is in evidence. The ruler is shown either standing or seated, bareheaded or wearing an elaborate turban. The dress is a simple garment thrown over the left shoulder, leaving the right shoulder and arm bare.

The 3rd dynasty of Ur is represented by very few stone sculptures. From the Isin-Larsa period there survive a number of life-size or nearly life-size statues of rulers of Eshnunna, which were carried away to Elam as booty and discovered by French excavators at Susa. Statues of several rulers of Mari also are known.

Of the Old Babylonian period rare examples of sculpture in the round are preserved. Hard stone such as diorite still was used. In contrast to the clean-shaven face represented on statues of Gudea, a head from this period, presumably of Hammurabi, shows an elaborately curled beard. From Old Babylonian times to the fall of Babylon, a period of over 1,000 years, only a few statues, of Assyrian kings, are known.

2. Small Sculpture and Amulets.—Even in prehistoric times animals or parts of animals occasionally were carved out of stone. In the Protoliterate period such small sculptures, beautifully carved, became very popular. They represent subjects that were of interest to the Mesopotamians throughout the ages—lions, panthers, domesticated and wild cattle, sheep, goats, pigs, birds, fishes, scorpions, etc. Occasionally the animals are depicted standing, but usually the domesticated animals are recumbent with their heads turned sideways. Such animal figures often have a flat surface at the back, and this is commonly engraved with holes forming outlines of quadrupeds or scorpions. The birds depicted in amulets are mostly ducklike. In addition to natural creatures there occur among the Protoliterate amulets examples of the lion-headed bird later known in Sumerian as Imdugud. Fishes occur either single or joined at the abdomen. Many of the amulets are perforated horizontally through the body but some are perforated vertically; the manner in which the latter type was used was ascertained when two such amulets were found

in situ at both ends of a string of beads.

Many of the great variety of amulets of the Protoliterate period continued into Early Dynastic times, when new popular forms also were added, among them stags, frogs, doves, fruits and leaves, and the representation of a bull or cow with an artificial beard. Occasionally such bearded heads were fashioned in couples in stone or gold. Outstanding examples of small sculptures in the historical periods are weights in the form of birds with their heads turned backward (duck weights), frogs, snails, boar's heads, etc.

3. Relief Sculpture.—No proper sculpture in relief is known from the prehistoric periods. A basalt stele from Warka shows hunting scenes, with figures whose garments and hairdress are characteristic of the Protoliterate period.

A more complex scheme of decoration in relief, on an alabaster vase from Warka, clearly depicts scenes of ritual character. The ritual has been interpreted as part of the wedding ceremony in which the goddess Inanna is offered bridal gifts by her consort Dumuzi (Tammuz). On other stone vessels of the Protoliterate period a common motif shows lions attacking bulls. The bodies of the animals usually are in low relief, with the heads often in high relief, sometimes approaching sculpture in the round. The body of a spouted vase from Warka bears this motif, while the spout is flanked by two lions sculptured in the round. Another common motif shows a naked hero between lions that attack cattle or sheep.

Numerous square or nearly square plaques decorated with reliefs are known from E.D. II and III. They usually are divided into three registers and have a hole in the centre. The upper register almost invariably depicts a banqueting scene in which a seated man and woman are attended by servants, musicians, dancers and gift bearers. The middle register usually shows bearers of gifts of various kinds. The theme on the lower register varies considerably, but a war chariot drawn by horselike animals (onagers?) often is depicted. The uniformity of certain aspects of culture over a wide area of Mesopotamia during the Early Dynastic period is illustrated by an incomplete plaque from Khafajah whose decoration could be completed by a fragment of a similar plaque from Ur.

The chief personages on E.D. plaques are human in most cases, but the fact that nearly all examples were found in temples indicates a religious significance. Some depict ritual scenes, such as libation offered by a naked priest in front of a seated god. A plaque from Telloh depicts the ruler Ur-Nanshe and his family. The ruler carries a basket on his head, presumably having assumed the humble and pious role of a labourer carrying material for the building of a temple.

The monumental "Stele of the Vultures" from Lagash commemorates the victory of the ruler, E-anna-tum, over Umma. One fragment shows E-anna-tum on foot, leading a phalanx of helmeted soldiers, and again in a chariot at the head of his army. The other side of the same fragment shows part of a large figure, probably the god Ningirsu, drawing a net filled with the bodies of the enemy, as the fowler draws a net around the trapped birds.

Sculptured stone vessels likewise continued to be made during the Early Dynastic period. One class, made mostly of steatite, is found in two forms: a low cylindrical cup with flat bottom, and a taller vase with incurving wall and a mouth somewhat narrower than the flat base. The earlier examples are of the E.D. II period. Several specimens bear a representation of a wattle structure, sometimes in combination with other motifs. On other specimens the decoration consists of more or less complex compositions of human beings, animals and plants.

From the Akkadian period has survived the magnificent and unique victory stele of King Naramsin. The king stands alone before a high mountain with heavenly bodies above. His army, represented by a small group of standard and weapon carriers, strides upward, while the enemy is represented by a few limp corpses, some of the enemy warriors in the agony of dying, and the still living asking for mercy. The whole expresses most concisely and eloquently the dramatic moment of victory. Fragments of other stelae and rock carvings of the Akkadian period, unlike the Naramsin stele, seem to have been composed in horizontal registers in the tradition of the Early Dynastic period.

The surviving fragments of a stele erected by Ur-Nammu, the founder of the 3rd dynasty of Ur, indicate that this monument commemorated the king's piety rather than his prowess. The best-preserved register shows the king approaching a seated god on the right and a goddess on the left. He is followed in each case by a female deity, presumably his personal goddess. This is the so-called presentation scene, which occurs in innumerable versions on cylinder seals of the Ur III and later periods.

Of the Old Babylonian period, the relief carved at the top of the stele inscribed with the code of Hammurabi should be mentioned. No ritual, indeed no action of any kind, is depicted. The king simply faces his god in testimony of divine sanction of his pious deeds.

During the Ur III, Isin-Larsa and Old Babylonian periods, a large number of clay plaques were made in molds. The commonest subject is the very old one of a nude female, usually with the arms under the breasts and occasionally with a child nursing, but gods and goddesses, bull-men, heroes fighting lions, hunters, wild and domesticated animals and various activities also are depicted. Some subjects are obviously of religious character, some have mythological connotations and others seem to be of secular nature. The manufacture of plaques in a mold had the obvious advantage of "mass production," which can turn out large numbers of a product while the artist concentrates on a single object, the original mold. Indeed, some of the molds are of exceedingly fine workmanship. While stone sculptures could be afforded only by a small segment of the society, the clay plaques represent a most important aspect of popular art.

Of the Kassite period a large number of boundary stones (*kudurru*) carved with reliefs are known. They usually show emblems of deities and often bear an inscription and sometimes also the representation of the king who granted title to the land or guaranteed the boundaries. Another type of relief, which occurs first in the Kassite period, is assembled from bricks, each brick being made in a special mold and forming part of a decorative motif or figure. The advantage of mass production is obvious here also.

Of the earliest independent Assyrian kingdom, in the 18th century B.C., very little is known. With the establishment of the Middle Assyrian state in the 14th century, a distinctive culture begins to emerge, blending western and northern influences with the cultural traditions of Babylonia. There is an essential difference between such ritual scenes as that shown in relief on an altar of Tukulti-Ninurta I, where the king first approaches and then kneels before an altar bearing the emblem of a god, and earlier works such as the relief carved above the code of Hammurabi, where the king confronts his god directly.

The major achievements of Assyrian art are the innumerable reliefs that covered the walls of the Assyrian palaces at Nineveh, Nimrud (Kalakh) and Khorsabad (Dur-Sharrukin). They provide an almost inexhaustible source not only for art studies but also for archaeological research, since the Assyrian artist delighted in depicting lifelike details of dress, weapons, chariots, horse trappings, buildings, cities, landscape features, etc. In contrast to early Babylonian reliefs, which are either explicitly ritual or have religious connotations, the Assyrian reliefs are mostly secular, constituting a pictorial testimony to the prowess and military might of the monarch. Even a peaceful scene showing the king banqueting with his queen to the sound of music bears a gruesome reminder of a recent victory in the form of the severed head of the enemy king hanging from a branch of a tree. The frequently shown symbols of deity, however, clearly imply that all the activity depicted takes place under the auspices and with the blessing of the gods.

During the *floruit* of late Assyrian art, between the 9th and 7th centuries B.C., there were appreciable variations in subject matter and style between the earlier and the later works as well as among reliefs from various locations. In spite of such differences, however, the whole of the late Assyrian bas-relief art is an entity in itself, individual and distinguishable from other major

classes of art in the near east.

In the relatively short time between the fall of the Assyrian empire, when the south regained predominance, and the fall of Babylon to the Achaemenids, a great cultural revival took place in the south and especially in Babylon itself. Glazed-brick decoration was lavishly used during Neo-Babylonian times to ornament important buildings. However, the very advantage of this technique for mass-producing colourful decorative motifs tended to reduce the number of such motifs and to make the whole decoration rather uninspiringly repetitious. Thus there was endless repetition of separate figures of the lion, the bull and the monster (each a symbol of a deity), framed with simple geometric motifs such as rows of rosettes or palmettes, but with no interaction between them.

4. Glyptic.—Buttonlike stone objects engraved with distinctive designs were commonly used as stamp seals in prehistoric periods. Many such stamps and also their impressions in clay are known. The designs are usually geometric motifs, though plants, animals and human figures begin to appear in the later prehistoric periods in northern Mesopotamia.

During the Protoliterate period in southern Mesopotamia engraved cylinder seals were introduced. Numerous impressions of such seals, made by rolling them on wet clay, have been found in excavations; indeed, some of the most interesting seals are known only from their impressions. Cylinder seals continued in use in Mesopotamia for over three millenniums and spread into other parts of the ancient world, where they sometimes assumed new iconographic and stylistic features characteristic of a particular region and period.

The earliest cylinder seals reveal a surprisingly high standard of glyptic art, rarely equaled in later times. A great variety of iconographic and stylistic beginnings were made. Plants, animals, human beings and monsters are depicted, together with man-made objects such as buildings, boats, symbols, utensils, etc. Sometimes the elements are arranged in symmetrical decorative motifs; often coherent action is depicted. Several iconographic elements are common to glyptic and other art forms. The scenes are on the whole ritual, though some impressions seem to show secular activity. Cylinder seals characteristic of the later phases of the Protoliterate period have been found outside Mesopotamia as far away as Egypt, providing important evidence for correlating certain phases of early Egyptian and Mesopotamian cultures.

The glyptic of E.D. I shows clear affinities in style and subject matter with that of the late phases of the Protoliterate period. Distinctive of E.D. I are seals of the "brocade style," in which the artist's aim was not to depict any scene or action but rather to produce an evenly decorated surface. The usual motif on such seals consists of horned animals.

The glyptic of E.D. II is distinguished by action scenes in which the decorative effect of the composition is of primary concern. Most of the scenes show conflicts between beasts, monsters and human beings in various combinations. The bull-man makes his appearance, usually siding with human beings in protecting cattle or sheep, and occasionally wildlife, from lions. Short inscriptions also appear. The composition makes use of antithetical groups and crossing bodies. The spaces between the contestants are filled with elements such as weapons, plants, separate heads and inscriptions, to produce an evenly filled surface.

E.D. III glyptic continues the subject matter tradition of E.D. II. The struggle between man and hero and lions attacking other animals is still a major subject, but a large variety of scenes depicting banquets (such as are shown on plaques), food and drink offerings, musicians, chariots, boats, etc., appear. Sometimes a deity, distinguished by the horned headdress, is depicted. Other seals show the building of a temple, apparently with the king participating as a humble labourer.

During the Akkadian period glyptic art reached a peak of perfection comparable only with that of the early stages of the Protoliterate period. The old theme of struggle between hero, bull-man and beasts is still popular, but it is rendered in an entirely new style. The figures are often articulate and finely modeled to render the actuality of musculature, hair, horns, etc. Very often the composition is heraldic, with a framed inscription as the central feature. A great variety of new subjects was introduced, many obviously mythological, though the specific myths to which they allude often are unknown.

With the fall of the dynasty of Akkad there was a marked decline in glyptic art. The Gutian occupation is represented by a few very poor specimens. From Lagash, under Gudea, and from many sites in southern Mesopotamia, which was reunited under the 3rd dynasty of Ur, there are numerous cylinder seals reflecting the mood of piety that so deeply permeates the other works of art of that time. Many specimens show a high standard of technical perfection, but there is a drastic limitation of subject matter during Ur III, with the so-called presentation scene predominating. This shows a worshiper being introduced to a god by another deity, usually a female, presumably his personal goddess. A short inscription frequently identifies the owner of the seal and the god to whom it is dedicated, but the god depicted on the seal is not necessarily the one to whom it is dedicated.

The glyptic of the Isin-Larsa and Old Babylonian periods continues the tradition of Ur III, with the presentation scene as its predominant subject. There are some variations, however; the god may be standing rather than seated, and the worshiper often is shown carrying an offering (usually a lamb or kid). The introduction of secondary elements in the spaces between the figures is characteristic. These elements, such as dragons, animals, nude females, monkeys, dwarfs and man-made objects, were apparently of amuletic significance.

In the Kassite period the subject matter of the cylinder seals is further impoverished. Very often only two figures, a god and a worshiper, are depicted, while the rest of the surface is devoted to a relatively long inscription—a prayer. Secondary elements occur between the inscription and the figures, most characteristically the Maltese cross. The Kassite seals are somewhat larger and longer than those of the Old Babylonian period, and instead of the previously popular hematite other, usually coloured, stones were used.

Contemporaneously with the later phase of the Kassite rule in the south, glyptic of the so-called Mitannian style appears in the north. In these seals an artificial material, glazed paste, often replaces stone. The Mitannian style is a peripheral development that penetrated certain areas of Mesopotamia and influenced Assyrian glyptic.

Middle Assyrian glyptic took over many of the earlier elements, but they are arranged with more balance and clarity. Many designs are known only from impressions. Scenes with human participants show not only ritual but also secular activities. Inscriptions often give the name of the seal's owner. Whether the seals depict fantastic creatures or a secular scene such as hunting there is a vigour of composition and a fine modeling of details that is comparable to the best specimens of Protoliterate and Akkadian glyptic. From this new peak Mesopotamian glyptic deteriorated in artistic quality, though some outstanding pieces were still produced during the New Assyrian and Neo-Babylonian periods. Ritual scenes, in which emblems often replace deities are predominant. There are also amuletic elements and undoubtedly astrological symbols. Hard stones such as rock crystal and chalcedony are commonly used, and the drill is employed in addition to the engraving tool.

5. Wall Paintings.—The earliest-known wall paintings were discovered in a temple of the Protoliterate period at Tell Uqair. Most of the motifs are geometric, consisting of rectangles and lozenges in various combinations. There are two leopards on the sides of the altar and traces of other quadrupeds and humans. The lower part of a human figure shows a colourfully decorated garment with tassels at the back.

Only a few indications of wall painting during the Early Dynastic period have been found.

For wall paintings dating to the first half of the 2nd millennium B.C. it is necessary to go outside Babylonia and Assyria proper to Mari on the middle Euphrates. These paintings are on the whole, in the tradition of Mesopotamian art, though they contain certain undoubtedly local elements. Painted presentation

scenes similar to those shown on the Ur-Nammu stele and on cylinder seals give some idea of the colourfulness of contemporary garments.

Numerous traces of wall paintings were found in the so-called "painted palace" in the Kassite city of Dur-Kurigalzu, near Babylon. They consist chiefly of processions of human figures placed, curiously enough, inside the doorways that cut through the thick walls of the palace. It may be assumed that other scenes were painted in other parts of the building. Approximately contemporary wall paintings were found at Nuzi, consisting of panels filled chiefly with geometric elements but including also stylized palmettes, bull heads and heads of the Egyptian goddess Hathor. These frescoes clearly show influences from farther west.

Nearly all the wall paintings known from Assyria come from palaces. Traces of both decorative motifs and representational design were found at Kar-Tukulti-Ninurta, of the Middle Assyrian period, located on the Tigris across from Ashur. The predominant colours are white, black, deep red and bright blue. Stylized flower motifs that originated in the regions west of Mesopotamia are common; the very old Mesopotamian motifs of rosettes and of animals placed symmetrically on each side of the "tree of life" also occur. The motifs are arranged in panels with more or less elaborate borders, the whole effect being that of tapestry. In later Assyrian towns similar motifs using the same colour schemes have been found. In addition, at Khorsabad (Dur-Sharrukin) traces of a huge panel depicting the king and perhaps one of his ministers before the god Ashur were found in the citadel that adjoined the main palace of Sargon II. This panel is placed above three rows of conventional designs showing bulls and winged genii in alternating rows. The uniformity of the elements suggests that the Assyrian painters may have used mechanical devices, such as templates. At Til Barsib, on the middle Euphrates, in addition to the normal decorative Assyrian motifs there were "narrative" scenes that parallel the stone bas-reliefs of the Assyrian palaces. Possibly wall paintings were only a cheaper substitute for reliefs.

6. Metalwork.—There are traces of worked metal, especially copper, from the late prehistoric periods. From the Ubaid period there survive copper beads, pins and needles as well as larger objects such as chisels and axes that seem to have been made in open molds and to imitate polished stone tools. In the Protoliterate period, copper, gold, silver and lead are known, though relatively few metal objects have survived.

The extraordinary variety and high technical perfection of the metallurgy of the Early Dynastic period are impressive. In addition to a great variety of tools and weapons, vessels, jewelry and ornaments, there are solidly cast (apparently by the lost wax or cire-perdue process) human and animal figures comparable in quality to the best examples of stone sculpture. The unique treasures from the royal cemetery at Ur illustrate the opulence of the early Sumerian civilization. Exquisite vessels, jewelry, a ceremonial helmet, weapons and animal heads were fashioned of gold and silver. Precious metals were combined with coloured stone, wood, engraved shell and mother-of-pearl inlays to produce highly complex and colourful creations. While copper was plentiful and often used to cast solid objects, large sculptures such as the lion heads from El 'Ubaid were made of bitumen cores covered with thin copper sheet on which the minor details were chased and engraved. A large copper relief from El 'Ubaid, depicting the lion-headed bird Imdugud gripping two stags, also combines bas-relief with heads fashioned in the round. A silver vase from Lagash is engraved on the body with a representation of Imdugud attacking lions and on the shoulder with recumbent bulls.

Outstanding among the surprisingly small number of major metal sculptures that have survived from later periods is a magnificent bronze head from Nineveh, assigned to the Akkadian period on stylistic grounds.

Small human and animal figures made especially for foundation deposits were sometimes accompanied by inscribed copper tablets identifying the builder and the building. In the human figures the lower part of the body was often replaced by a peg. Another type of metal figure used in foundation deposits is a kneeling deity holding a peg. The custom of using metal figures in foundation deposits, observed at the end of Early Dynastic III, was followed by Gudea and by kings of the 3rd dynasty of Ur. Statuettes of Ur-Nammu and Shulgi represent the king as a labourer carrying a basketful of building material on his head. Ur-Nammu's statuettes usually have a long flaring skirt, but Shulgi's statuettes are of the peg type. Two unique four-faced copper statuettes represent a standing god and a seated goddess. They were found at Ishchali and date from the Isin-Larsa period.

Of the subsequent periods in Babylonian history little sculpture in metal is known, but from the Assyrian empire period major works of art have survived. Most important are reliefs in bronze that decorated some of the Assyrian palace gates. The subject matter of the reliefs from Balawat, near Nimrud, parallel that of stone bas-reliefs portraying military campaigns. Fragments found at Khorsabad show motifs that appear also on panels of glazed bricks—the bull, the eagle, the plow and the fig tree. Whether these elements are astrological symbols or a peculiar rendering of the king's name is uncertain.

Iron was used in Mesopotamia after about the middle of the 2nd millennium B.C., and large quantities of iron objects were found in the Assyrian palaces when they were first excavated in the middle of the 19th century. Isolated finds indicate that blades made of terrestrial iron occurred as early as the middle of the 3rd millennium B.C.

7. Inlays and Engravings.—As early as the Protoliterate period stone vases were embellished with multicoloured inlays, the motifs being rosettes in which petals of two colours alternated (usually red and white); concentric circles, also of alternating colours; and geometric motifs consisting of rows of triangles and lozenges. The inlay pieces were held in place by bitumen or red paste, which occasionally formed part of the colour scheme. For architectural decoration, so-called "cone mosaic" was used in the Protoliterate period. The heads of small terra-cotta cones coloured white, black, red and occasionally yellow produced geometric patterns on walls and columns that were similar to the geometric patterns of the inlays and also to the patterns of the contemporary painted pottery. To circumvent the difficulties that arise in applying cone mosaics in corners and quoins, terra-cotta tiles impressed with circles to imitate the cone heads were employed. Tiles with representations of animals, also impressed with circles, were combined with cone mosaics.

Though the use of cone mosaic apparently was confined to the Protoliterate period, other types of inlaid decoration continued in the Early Dynastic period. Inlays of coloured stone, shell, mother-of-pearl and occasionally paste were applied to stone vessels, musical instruments and a variety of other objects. Dark-coloured stone plaques were inlaid with figures of light-coloured stone, shell and mother-of-pearl. Almost invariably the eyebrows and eyes of statues also were inlaid. The details on the inlays themselves often were engraved and the lines filled with red or black pigment. On the so-called standard from Ur both the background and the figures consist of inlays. On the obverse are three registers of battle scenes, while the reverse depicts a victory banquet in three registers. The Ur standard apparently is a secular monument, but inlaid decoration also was inspired by rituals, myths and, perhaps, fables. No comparable mosaic monuments are known from later periods.

8. Ivories.—Ivory carvings are found only occasionally in Mesopotamia. Early ivory objects may have been made out of wild boars' horns. Few small ivory carvings are known from the Early Dynastic period, and ivory seems to have disappeared until the 2nd millennium. A great wealth of ivory objects is known from the Assyrian imperial period from practically all the major sites but especially from Nimrud. While the character and origins of the prehistoric ivory are uncertain, there is no doubt that in historic times true ivory was imported, possibly first by the southern sea route (the Persian gulf) and later, into Assyria, from the west (mostly, perhaps, by way of the Mediterranean). Plant motifs of the west are recognizable in Assyrian ivories. Indeed, a large proportion of the carved ivories found in Assyria are non-Assyrian in style and are the product of western craftsmen.

C. Utilitarian Objects

1. Tools and Weapons.—In the earliest village cultures of Mesopotamia flint and obsidian blades and core tools are numerous, as are ground or polished stone implements. Stone bowls and cups of rather sophisticated shape were found in Jarmo at levels in which pottery was yet unknown. Bone tools also are found in the earliest excavated settlements, occasionally hafted in a lump of clay or bitumen. Of exceptional interest among the Jarmo finds are very delicate small bone spoons with elaborate handles. Bone tools continue without much change even into historical periods.

Traces of metal were found in the early village remains, but not until the Ubaid period do substantial copper tools such as chisels and axes appear. Likewise characteristic of the Ubaid period are terra-cotta sickles and fairly elaborate stone hammers or hammer axes. Rounded stone objects perforated through the long axis, which are referred to as mace heads or club heads, also appear in the prehistoric periods. Use of the bow and arrow and the spear in the Protoliterate period is attested by representations on monuments.

In the Early Dynastic period, chipped and polished stone tools continued, as did simple bone tools. Sickles consisting of several serrated flint blades set in wood with bitumen have been found *in situ*. The rapid development of metallurgy is reflected in the great variety of copper tools and weapons. In addition to battle-axes there were many types of adzes, daggers, knives, swords, spear points, harpoons, etc. Ceremonial weapons, a number of which were found in the royal tombs of Ur, were made of precious metals. Shields and helmets are depicted on monuments.

During the Akkadian period stone tools and weapons were still used. The metal objects were inferior to those of the Early Dynastic period, being made of relatively thin sheet metal bent and hammered to the desired shape. Representations of the bow and arrow reappear on monuments, though the battle-ax, mace, sword and spear continued in use. A laurel-leaf-shaped flint arrowhead is characteristic of the Akkadian period. The plow is often depicted on Akkadian cylinder seals, and copper parts of plows, as well as hoes and shovels, are known from later periods.

After the Akkadian period the bent scimitar was introduced. The figure of a four-headed god from Ishchali holds such a weapon, which is often depicted also on terra-cotta plaques and cylinder seals.

Assyrian reliefs show individual armour as well as large shields for protecting battering rams. The straight sword replaced the curved scimitar.

2. Personal Ornaments, Cosmetic Articles and Dress.—Simple beads of stone and shell were used in all periods. In Early Dynastic times gold and silver ornaments must have been very abundant, to judge, for example, by the great number discovered in the royal tombs at Ur. In addition to the softer stones, rock crystal, lapis lazuli, agate and carnelian were employed for beads of various shapes. Carnelian beads occasionally were etched to produce a white design. This technique also was used in the Indus valley, and it provides one of several links between the Indus and Mesopotamia at the end of the Early Dynastic period.

Relatively little jewelry has survived from later periods, and most of the information derives from representations. Clay plaques of the Isin-Larsa and later periods show that strings of beads were worn by both men and women. Occasionally bracelets are shown. In Assyrian art deities and monsters as well as men and women are shown wearing earrings, beads, armlets and bracelets.

Stone palettes with traces of paint indicate the use of cosmetics in the earliest village communities. Surprisingly modern-looking ivory combs and an ivory hairpin inlaid with lapis lazuli, turquoise and gold bands were found in early tombs at Tepe Gawra. The royal tombs at Ur yielded a large number of cosmetic containers and toilet articles. Gold and silver toilet sets consisted of a ring to which were usually attached one pointed and one chisellike object, a pair of tweezers and a minute spoon, perhaps an ear scoop. Such sets were kept in elaborately decorated conical cases. Similar toilet sets of copper come from Early Dynastic levels at other sites. Lumps of black, red and orange paint used as cosmetics have been found in sea shells, in miniature stone vessels and in copper, gold and silver containers imitating shells. Copper razors also are known. Fewer cosmetic and toilet articles are known from later periods, but on the whole they seem to be of types similar to those of the Early Dynastic period.

No clear representations of dress are known from the prehistoric periods. Paint lines on terra-cotta figurines may indicate either garments or tattoo marks. The large number of spindle whorls recovered from prehistoric sites would indicate that spinning and weaving were known.

Garments are clearly depicted on reliefs and glyptic of the Protoliterate period. Some men, usually beardless (perhaps young adults), are represented as bare to the waist and wearing a short skirt. A diaphanous skirt reaching to the knees or the ankles is worn by a dignitary who invariably has a beard, long hair falling to the shoulders and a fillet on the head. The typical female costume is a beltless garment covering the left shoulder and fastened under the right arm, leaving it free; this garment, which shows a finished hem, continues into much later times. In Early Dynastic times a garment that leaves only the right arm and shoulder uncovered is worn also by male dignitaries and deities.

Sculpture and glyptic of the Early Dynastic period frequently depict a skirt reaching below the knees and held by an elaborately tied and fairly thick girdle. Female figurines invariably wear a long garment that covers the left shoulder. The representations of the Protoliterate period show smooth, loosely woven textiles, whereas those of the Early Dynastic period show mostly tufted materials. Apparently no outer garments were worn normally. Soldiers are represented as wearing capes of a heavier material (leather) for protection. No shoes are represented before the Akkadian period.

Gudea statues show the early type of costume in its severe simplicity. The right arm is uncovered, and two or three folds hang from the left arm. Occasionally the hems are decorated. In the Isin-Larsa period garments covering both shoulders appear. The royal statues from Mari show either the old-fashioned dress with the right arm and shoulder uncovered, but with more elaborately tasseled and fringed edges, or a garment covering both arms and shoulders.

Glyptic of the Akkadian and subsequent periods shows a great variety of garments, differing mainly in the decoration of the edges and in the vertical folds. Some have tiers, which indicate either that the dress was sewn from a number of horizontal bands or that such bands were wound and fastened to an undergarment.

Assyrian bas-reliefs of the 9th to 7th centuries B.C. also show a great variety of garments of king, courtiers, soldiers and foreigners. In keeping with the earliest traditions, the king's garment often reaches to his feet; similar garments are worn sometimes also by deities and demons. They are often shown as worn over a short skirt which would allow freedom of action when the long garment is open. The soldiers usually wear short skirts. Sandals are very commonly depicted on Assyrian reliefs.

3. Pottery.—Apparently the earliest-known pottery in Mesopotamia is that from the sixth level at Jarmo, but even at this early stage there was considerable variety in the forms as well as in the decoration with red paint.

In the Hassuna period the number of shapes increased, and incised and painted decorations were used. Toward the end of this period appeared a class of pottery known as Samarra ware, the sophisticated monochrome-painted decoration of which has considerable artistic merit.

Pottery of the Halaf period is distinguished by characteristic forms, some of them recalling metal types. The decoration is polychrome, with black and red paint used on a buff or white background. The motifs are mainly geometric. In contrast to the Samarra ware, the designs are symmetrical and often crowded. Even the representational motifs, such as bucrania (*i.e.*, ox skulls), were gradually reduced to abstract patterns.

Pottery of the Ubaid period has been found not only throughout Mesopotamia but also in western Iran and the Mediterranean area. The decoration is usually monochrome, with dark paint on a light background. A great variety of forms and painted patterns was

used.

Following the Ubaid period in southern Mesopotamia, new types of pottery emerged along with other classes of objects that represent the earliest phase of the distinctively Babylonian culture. After a relatively short phase characterized by burnished black, gray and red pottery, the so-called Jamdat Nasr ware appeared, having both monochrome and polychrome painted decoration, each type applied to specific forms. Following the Jamdat Nasr ware there appears in E.D. I a new class of polychrome painted pottery known as Scarlet ware. In addition to geometric patterns such as are seen on Jamdat Nasr pottery, the Scarlet ware has a large variety of representational motifs depicting plants, animals and human beings, occasionally grouped so as to form a coherent scene. This type of pottery apparently continued into E.D. II. A vase in the British museum that depicts a chariot, musicians and a banqueting scene probably dates from the early part of E.D. III.

Alongside painted pottery there was in every period a large variety of plain vessels and others with plastic, incised or engraved decoration. Typical of E.D. III are jars with upright handles on which the features of a nude female are usually indicated, either in relief or by engraving.

With minor exceptions, Mesopotamian pottery remained unpainted until glazing was introduced in the beginning of the 1st millennium B.C. However, distinct groups of decorated pottery occasionally appear. Gray jars decorated with white-filled engravings in the Isin-Larsa period show simple geometric designs alongside birds, quadrupeds, boats and human figures. Other groups of pottery, found in the north, are the Habur ware of the Old Assyrian period and the white-painted Mitannian ware that originated farther to the west.

All through Mesopotamian history new shapes were being developed and, in turn, abandoned to be replaced by other forms, and these forms, though undecorated, are invaluable for the dating of the material remains among which they are found.

4. Musical Instruments.—It is possible that musical instruments made of perishable materials (reeds) were used in prehistoric times, but the earliest preserved musical instruments are bone pipes of the Ubaid period from Tepe Gawra.

The earliest representation of an "orchestra"—that is, musicians playing simultaneously string, percussion and wind instruments—is preserved on a fragment of a steatite vase from Adab. Musical instruments are depicted on plaques and cylinder seals of the Early Dynastic period. The actual musical instruments discovered in the royal tombs at Ur show the lavishness with which such instruments were decorated. The animal heads at the end of the sound boxes were made of gold or silver and decorated with semiprecious stones. The sound boxes and the uprights of the instruments were inlaid with multicoloured mosaics of semiprecious stones, shell and mother-of-pearl. The inlaid plaques themselves were engraved with delicate designs filled with black or red paste.

Some of the mold-made terra-cotta plaques, which represent the popular art of Mesopotamia in later periods, depict musicians playing various instruments (large and small harps, lyres, lutes, cymbals, etc.). On the Assyrian reliefs musicians and musical instruments are often represented as part of a ritual (king pouring libation over lions), during processions (capture of Susa by Ashurbanipal) and, naturally, in banqueting scenes. Frequently the musicians are foreigners or people wearing a foreign type of dress.

5. Lamps.—It is uncertain when the inhabitants of Mesopotamia thought of a special device to obtain a portable light at night. A peculiar jar with seven spouts, two specimens of which (belonging to the Protoliterate period) were found several hundred miles apart, may indeed have been used as lamps. In the Early Dynastic period large sea shells were cut lengthwise and the containers thus obtained used for lamps, the wick being laid in the channel at the narrow side of the shell. Stone, clay and metal (including gold and silver) lamps imitating the form of shell lamps were common toward the end of the Early Dynastic period. Occasionally a ring was added to the narrow end to hold the wick in place. Stone lamps often were decorated in relief with representations of an animal or bull-man. This type of lamp continued until the Old Babylonian period when a lamp with a closed wick channel was introduced. This consisted of a small jar to which a wide spout was added; in later periods it assumed a shoelike shape. Such lamps are clearly shown among the symbols of deities on boundary stones of the Kassite period. Occasionally they are depicted on top a special stand. With the introduction of glaze, lamps as well as other pottery utensils were normally covered with glaze.

6. Boats.—The two great rivers are the dominating geographical features of Mesopotamia, and the inhabitants from earliest times used them as main transportation routes. Since materials from which boats are normally made are perishable in the climate of Mesopotamia, all information about ancient boats depends on models and representations on monuments. The earliest model of a boat, from the Ubaid period at Eridu, has a hollowed shaft in the centre; this has been interpreted as a base for a mast and consequently as evidence for the use of sailing boats in prehistoric times. No sails are depicted, however, on any of the numerous representations of boats in later times. Boats represented on cylinder seals of the Protoliterate period are long and low with high upturned prow and stern, a type that persists throughout Mesopotamian history. Punting poles as well as oars with wide, leaf-shaped blades are frequently shown. Occasionally both prow and stern end in plant forms. At the stern there is sometimes an upright member that apparently is tied to the boat.

In the Early Dynastic periods, in addition to numerous representations on seals, boats are shown also on votive plaques, and actual models made of clay, bitumen and metal are known. A silver model boat, over two feet long, from the royal cemetery at Ur shows a series of oars, cross members and a loop over which a cloth could be stretched to form shelter from the sun. In many representations of boats on cylinder seals of the Akkadian period deities are shown riding. Occasionally the prow of the boat itself ends in a figure of a deity using a punting pole.

Numerous clay models and representations of boats from later periods do not differ essentially from those of earlier times. In the Assyrian reliefs innumerable representations of boats and rafts are shown, but the general character of the boat remains unchanged. Occasionally the prow ends in a horse's head. Nowhere is the contrast between the river boats of Mesopotamia and the seagoing boats of the western Mediterranean more clearly shown than on a relief of Sennacherib on which both types are depicted.

7. Chariots.—The war chariot apparently made its first appearance at the end of the Early Dynastic I period, and is frequently depicted on Early Dynastic III monuments. A copper model from the Early Dynastic II period was found at Tell Agrab. It is impossible to say whether the chariot was a Mesopotamian invention or whether it was introduced from the outside. Neither is it possible to identify with certainty the animals that were used in harness. The harness itself consisted of a yoke fastened to a central pole.

Two-wheel as well as four-wheel chariots were used, and a model of a covered-wagon-type chariot, found at Tepe Gawra, indicates a peaceful use of the chariot. Assyrian reliefs depict war chariots as well as ox carts in great detail.

D. Tombs and Burials

Disposal of the dead was a concern of the inhabitants of Babylonia and Assyria from earliest times, and inhumation was practised throughout the land in all periods. Occasionally traces of fire are discernible in burials, but there is no evidence that cremation was at any time the prevailing custom. From prehistoric times the dead were supplied with objects such as pottery and personal possessions and apparently with food and drink on a more or less lavish scale. Indeed, objects found in burials form the major part of the archaeological material from Mesopotamia; those from the royal cemetery at Ur, for example, are among the richest and most important finds ever made in the country (*see* Ur). Burials varied from simple inhumation in a hole dug in the ground to specially constructed elaborate tombs that indicate

a complex and prolonged burial ritual. The body was laid either extended on its back or in a more or less contracted position on either the right or the left side. No special orientation toward any point of the compass seems to have been preferred. Graves sometimes were located in cemeteries outside the living quarters and sometimes under the floors of houses. Similarly, burials occurred sometimes within a temple precinct, while in other instances not only were burials in temples avoided but, apparently, great effort was spent to clear the area on which a temple was to be built of earlier traces of habitation as well as of graves. What guided the preference for one custom over another cannot be ascertained. (P. P. D.)

III. HISTORY

A. Early Periods

1. Prehistory.—The foothills of the Zagros mountains in northern Iraq, the country later known as Assyria, seem to have been one of the regions where villages based on agriculture and flock raising first developed. One of the early sites is Jarmo (*q.v.*), whose first levels antedate the invention of pottery. A more advanced village culture, named after the type site Hassuna (near Mosul), is found all over upper Mesopotamia. The following still more elaborate stage, in which copper makes its first appearance, is called the Tell Halaf culture after a site near the source of the Khabur river, but its centre was in the Mosul area; it covered a large area, from Assyria to southeastern Turkey and the Mediterranean. Farther to the southeast there existed a similar but slightly older culture named after the type site Samarra on the middle Tigris. These two cultures, whose most outstanding artifacts are their beautifully painted clay vessels, were replaced by the culture called Ubaid. This name is taken from a site near Ur in southern Babylonia, but the Ubaid culture covers all of Mesopotamia as far as Cilicia and the north Syrian Amuq plain (the Turkish province of Hatay) and has relations with similar culture stages on the Iranian plateau.

In spite of certain differences in detail between northern and southern Ubaid, the over-all picture is one of great homogeneity over the entire area from the Persian gulf to the Mediterranean sea.

In Babylonia—the alluvial plain downstream of Baghdad—Ubaid was for a long time believed to be the oldest culture. Excavations in the 1930s and 1940s, however, showed that earlier settlements existed there too, especially at Eridu, a city that was credited with high antiquity also in Babylonian tradition. Whereas the exact time relation of the early settlements in the south to those of the Halaf and Samarra cultures in the north has not been established, it seems clear that on the whole human settlements appear much later in the alluvial plain than in upper Mesopotamia. (*See* Archaeology.)

2. Protoliterate Period in Babylonia.—After the widespread and fairly homogeneous Ubaid culture, the north and south underwent different development. Whereas in the north the periods following Ubaid, called Gawra (after the type site Tepe Gawra) and Ninevite, brought few innovations, the south made the decisive step to higher civilization in the next major period, for which the name Protoliterate has been introduced. According to the older terminology, in which archaeological periods are named after type sites, the period called Protoliterate corresponds to the last phases of the Warka period (Archaic level IV in Warka) and the Jamdat Nasr period (Archaic level III in Warka). The term Protoliterate was chosen because in this period writing makes its first appearance (Warka IV). The first written documents are small clay tablets inscribed with accounts and found in the precinct of Eanna, the main sanctuary of Erech, thus probably representing an early form of accounting for the type of temple economy known from later times. The writing is pictographic: pictures of various animals, parts of the human body, grain, vessels, etc., were incised with a pointed stylus in the soft clay before it was dried in the sun. Numerals were expressed by circular (for the tens) and semicircular (for the units) impressions of the round end of the stylus. Purely conventional symbols were used alongside pictures from the beginning. Although many of the pictographic signs can be identified with later cuneiform forms, the majority of the pictographic texts are not fully interpreted. Some peculiarities make it clear that the second group of pictographic texts (Warka III, Jamdat Nasr) was written in Sumerian, and the same is probably true of the first group (Warka IV). This would indicate that the Protoliterate civilization was developed by the Sumerians, the people still leading in Babylonia in the 3rd millennium. The origin of the Sumerians is unknown. Their language, of agglutinative structure, cannot be linked to any known family of languages. (*See* Cuneiform; Sumerian Language.)

That the Sumerians were not the earliest settlers of southern Babylonia is shown by linguistic analysis: the names of the oldest cities are pre-Sumerian, and so are the words for the basic crafts and agricultural activities, which were borrowed by the Sumerian language from an earlier language. From the appearance of the first Sumerian texts in the Protoliterate period it has been concluded that this period marked the arrival of the Sumerians in the country; but this conclusion is contested by some scholars who would date it still earlier.

B. First Historical Periods

1. Early Dynastic Period.—For the archaeological levels following the Protoliterate period the name Early Dynastic has been introduced. This term is based on the fact that, roughly at least, this period seems to correspond to the time in which the later Sumerians placed their first "dynasties." The word dynasty was introduced in modern times; Sumerian tradition speaks of the kingship that came down from heaven and existed in various cities, passing at different times from one city to another. Since the succession from father to son was not continuous at all times, the term dynasty is inaccurate, but it has come into general use. Furthermore, whenever the "kingship" returns to a city that had it before, modern scholars have introduced a numbering system by which they speak, *e.g.*, of the "1st, 2nd, etc., dynasties of Kish" or of other towns. The arrangement of all dynasties in one single time sequence in the Sumerian king list is fictitious; modern criticism has shown that the various royal centres existed simultaneously, so that the total time covered by the list has been considerably reduced.

The Sumerian king list, which found its final form as late as the early 2nd millennium (original composition around 2100 B.C. is debated), distinguishes between kings "before the Flood" and "after the Flood," thus linking the historical tradition to the belief in one universal "Flood" (*see* Flood [in Religion and Myth]). This tradition, which was still known to Berossus in the 3rd century B.C., seems also to have influenced the biblical account of the generations from Adam to Noah. The king list knows of ten antediluvial kings, each with a mythical reign of tens of thousands of years, who ruled successively in the cities of Eridu, Badtibira, Larak, Sippar and Shuruppak; Shuruppak was also the place where later tradition localized the advent of the Flood. Excavations led to the discovery of deposits of silt and sand overlying inhabited deeper levels, which presumably represent a flood, in various towns and in different depths. Whereas the "flood level" of Ur falls into the Ubaid period, similar "flood levels" in Kish and Shuruppak (Tell Fa'rah) separate the Protoliterate from the Early Dynastic level. It is therefore impossible to identify the antediluvian age of ancient tradition with any given archaeological period.

The first town that is said to have had the "kingship" after the Flood is Kish (1st dynasty of Kish). According to T. Jacobsen's synchronic reconstruction, the latest part of this dynasty was contemporary with the 1st dynasty of Uruk, which was founded by a son of the sun-god. Among his successors, the names Enmerkar, Lugalbanda and Gilgamesh (*q.v.*) are those of the heroes of Sumerian epics, whereas Dumuzi was known as a god (Tammuz), the lover of Inanna.

If Jacobsen's reconstruction of the data underlying the Sumerian king list is correct, the kings of Uruk just mentioned fell only a few generations before the beginning of the 1st dynasty of Ur, whose first king also is known from authentic inscriptions. Still earlier is the first preserved royal inscription, that of a certain

Me-silim, king of Kish, whose name does not appear in the list. He is said to have arbitrated a boundary dispute between the south Babylonian cities of Lagash and Umma, whereas his own capital, Kish, is situated in the north of Babylonia. The fact that he had such powers tallies with the tradition that Kish was the seat of the first postdiluvian dynasty and with the still unexplained phenomenon that the title "king of Kish" seems later to have come to mean "king of the universe."

The first rulers of the 1st dynasty of Ur (about 2550 B.C. according to a rough estimate) are known from the "royal tombs" discovered at Ur and from a temple at El 'Ubaid as well as from the king list (although some of the kings whose inscriptions were found at El 'Ubaid do not appear in the king list). This period is the first historical period of Babylonia and the latest part of the Early Dynastic period (Early Dynastic III, whereas I and II are older). The tombs and buildings attest a high level of material culture.

Roughly contemporary with these kings of Ur were local rulers of Lagash, who do not appear in the king list. The reason for this omission may be the fact that they did not bear the title *lugal* ("king") but rather called themselves *ensi*. This term (formerly read *patesi*) has been interpreted in different ways and also has different meanings in various periods. The title seems to imply subordination of its bearer under a higher authority, sometimes a king (*lugal*), so that at times *ensi* means no more than "governor," sometimes a city-god who is regarded as the real ruler while the *ensi* is his earthly representative. A long sequence of early *ensi* of Lagash is known from their own inscriptions, and at least some of them seem to have been practically independent though perhaps in theory under the suzerainty of some "king." The first known *ensi* of Lagash, datable to about the time of the first part of the 1st dynasty of Ur, is Ur-Nanshe (formerly misread Ur-Nina). His second successor, E-anna-tum, has left the famous "Stele of the Vultures" in which he commemorated his victory over the neighbouring city of Umma. Among E-anna-tum's successors, mention may be made of En-anna-tum I, En-temena and En-anna-tum II. After two more rulers, the last in the series of early *ensis* of Lagash is Uru-ka-gina, who is best known from his "reform texts." He tried to protect the poor, the widows and orphans by reducing the powers of the priests and of the royal officials.

Toward the end of Uru-ka-gina's reign (about 2375 B.C.) a certain Lugalzaggesi, *ensi* of Umma, conquered and destroyed Lagash. He then also defeated Uruk and Ur and made himself king in Uruk (he alone represents the 3rd dynasty of Uruk). According to his own inscriptions, Lugalzaggesi not only united all of Sumer including Kish but also carried his conquests as far as the coast of the Mediterranean sea. He thus was the first empire builder, and this period has therefore been called "protoimperial." After a reign of 25 years, however, Lugalzaggesi lost his empire to a still mightier conqueror—Sargon.

2. Dynasty of Akkad.—Semites must have been the neighbours of the Sumerians from very early times, as is evidenced by Semitic loan words in Sumerian. A Semitic dynasty is attested for Mari (Tell el Hariri on the middle Euphrates) for the Early Dynastic period. The questions of whether Semites were present before the arrival of the Sumerians and of their numbers in Early Dynastic times are not solved. It may be assumed that they came out of the Arabian desert and settled on the fringes of the cultivated land; they seem to have appeared first in large numbers in the north of Babylonia. By the time of Lugalzaggesi they must have been strong enough in the north so that one of their leaders could establish himself as king in the north Babylonian town of Akkad (not identified with any mound).

The Semitic ruler who thus established the dynasty of Akkad called himself Sharrum-kin, "the king is legitimate"; from the fact that a later namesake, Sharru-kin II of Assyria, appears as Sargon in the Bible, the form Sargon is used for the king of Akkad also. Sharrum-kin or Sargon of Akkad became the central figure of an extensive literature in later times, and one of these literary texts is the legend of his birth: he was an illegitimate child, was put into the river in a box by his mother, found and raised by a gardener of the king of Kish, and by the favour of the goddess Ishtar became cupbearer of that king until he finally took his throne. Although this is legend (of the type of the Moses story), the fact that in his own inscriptions Sargon never mentions his father seems to confirm his lowly birth, and the name, which claims legitimacy, may have been chosen for just that reason.

After having dethroned King Ur-Zababa of Kish, Sargon defeated Lugalzaggesi of Uruk and thereby conquered the whole of Sumer to the Persian gulf, in which he "washed his weapons." He then extended his empire in all directions, conquered Elam in the east and the western regions along the upper Euphrates to the Mediterranean. According to his own inscriptions Sargon reached the Amanus and Taurus mountains; a later literary text lets him even cross the latter and reach the Anatolian plateau, but the historicity of this event is debated. The new capital, Agade, founded by Sargon, thus became the centre of a vast empire, to which ships brought riches from distant countries across the Persian gulf and up the river. The king list gives Sargon's reign as 56 years (about 2350–2300); toward the end of his rule a revolt occurred in his own country.

Sargon was succeeded by his two sons, Rimush and Manishtusu (the total of their combined reigns is 24 years), and the latter was followed by Sargon's grandson Naramsin (37 years; the four reigns together cover 117 years, *c.* 2350–2230). Later tradition omitted Rimush and Manishtusu and made Naramsin a son (instead of grandson) of Sargon. Naramsin was another great conqueror under whom the empire reached at least the same size as under Sargon. He built a palace in Tell Brak, northwest of Mosul, and an inscribed stele of his was found near Diyarbakir on the upper Tigris. His most famous monument, however, is a stele commemorating his victory over the Lullubi, a barbarian tribe in the Zagros mountains on the border of Elam.

Although Naramsin was followed by a king with the boastful name Sharkalisharri, "king of all kings," and six other, little-known rulers, tradition links the downfall of the dynasty with Naramsin's name, and it is possible that this tradition is correct. A barbaric people from the east, the Guti, invaded Babylonia and destroyed both the kingdom and the city of Akkad.

Under the kings of Akkad, their Semitic language, known as Akkadian, became a literary language, written with the cuneiform system of writing. The Sumerian language continued in use beside Akkadian; some of the royal inscriptions are bilingual. (*See* CUNEIFORM; AKKADIAN LANGUAGE.)

There was no racial antagonism between Sumerians and Akkadians; the kings of Akkad were accepted as the legitimate rulers of Sumer (the southern part of Babylonia) as well as of Akkad (the northern part).

Art reached its peak under the dynasty of Akkad. Unfortunately nothing of the literature of the time has survived.

3. Dynasty of Guti.—As noted above, the Akkadian empire was destroyed, either at the end of Naramsin's reign or later, by the invasion of a mountain people from the east, the Guti. Tradition has kept the memory of the destruction brought by them over the entire country, and the king list gives the foreign-sounding names of their rulers, whose reigns came to a total of about one century (*c.* 2230–2130). In fact, however, they seem not to have held all of Babylonia at all times, since, apart from the last kings of Akkad who may have continued a limited rule in the north, the so-called 4th dynasty of Uruk seems also to have been contemporary with the dynasty of Guti.

Another independent ruler whose reign probably falls into the latter part of the Guti period was Gudea, *ensi* of Lagash in the south. Under him that city had its golden age. Apart from outstanding works of art (*see* above, *Archaeology, Architecture and Art: Sculpture*) he left a number of inscriptions in Sumerian on his statues and on clay cylinders. The language of his inscriptions is considered "classical" Sumerian. He describes in great detail the building and inauguration of a temple for his god Ningirsu, for which he got cedar beams from the Lebanon.

A king of Uruk by the name of Utukhegal, who is counted as the only king of the 5th dynasty of Uruk, was credited with the liberation of the country from the Gutian yoke. Under him, a certain Ur-Nammu was *ensi* of Ur, but soon Ur-Nammu dethroned

his overlord and united the whole country under the rule of the city of Ur, thus establishing the 3rd dynasty of Ur, which lasted for another century.

4. Third Dynasty of Ur.—The liberation had been the work of the Sumerian Utukhegal, and under Gudea Sumerian civilization reached its classical phase. The newly established 3rd dynasty of Ur brought the Sumerian element in the country once more into political predominance. The kings of Ur are: Ur-Nammu (18 years, beginning *c.* 2130), Shulgi (formerly misread Dungi, 48 years), Amar-Sin (also read Bur-Sin, 9 years), Shu-Sin (formerly misread Gimil-Sin, 9 years) and Ibbi-Sin (25 years; the later part of his reign, however, overlaps with other newly emerging dynasties).

Although the Sumerian language was predominant throughout the period, Akkadian remained in use, and persons bearing Akkadian names are mentioned frequently. A gradual shift from Sumerian to Akkadian also may be observed in the names of the kings, who form a real dynasty in the sense of uninterrupted father-son succession. Whereas the first two names are Sumerian, the last two are Akkadian; the third is either Akkadian (if the reading Bur-Sin is correct) or, more probably, hybrid, Amar being Sumerian and Sin being the Akkadian name of the moon-god, the city-god of Ur.

The 3rd dynasty of Ur held a real empire, firmly administered by governors (*ensi* in this period having this meaning), both in the various Babylonian cities and in outlying territories such as Elam, Eshnunna and Ashur. The kings of Ur indulged in great building activities; canals and temples were built throughout the country, and some of the ziggurats or temple towers still standing in ruins were the work of these kings, particularly the first two, Ur-Nammu and Shulgi.

The king was regarded as a god during this period. In contrast with practice in Egypt, whose Pharaoh was a god at all times, the custom of deifying the king existed in Babylonia for a limited time only. In writing, the divine determinative (*i.e.*, the word sign for "god" written in front of the name) served as an expression of this belief. In the dynasty of Akkad this determinative was used with the names of Naramsin and Sharkalisharri; under the dynasty of Ur it was applied to all kings. In addition there are hymns addressed to several kings of Ur in the style of hymns to a god, and the figure worshiped in the adoration scenes on seals also has been interpreted as the deified king. After the 3rd dynasty the custom lived on for a while (under the first kings of Isin and Larsa, *see* below), but it soon fell into disuse; beginning with the classical Old Babylonian period deification of a Babylonian or Assyrian king is no longer found.

The economy was organized by the state. Most of the arable land was the property of the crown; labourers received rations from the crops delivered to the royal storehouses. For the administration of this vast state economy a very differentiated hierarchy was developed, and records were kept of all deliveries and distributions of rations. Tens of thousands of clay tablets inscribed with such records were found in the capital Ur itself, in Lagash, Umma and in a royal dairy farm called Puzrish-Dagan (Drehem). Foreign trade also was carried out in the name of the central administration.

During the rule of Ibbi-Sin, the empire crumbled. In one city after another documents ceased to be dated with his date formulas. In Ur there was famine, prices rose and the government had to buy grain at high prices from different regions. Two former officials seem to have made themselves independent kings, Naplanum in Larsa and Ishbi-Irra in Isin. The final blow to Ibbi-Sin came through an attack from Elam; Elamites conquered Ur, where they kept a garrison for a few years.

C. Old Period (Babylonia and Assyria)

1. Dynasties of Isin and Larsa.—With the establishment of Naplanum and Ishbi-Irra *c.* 2030 there begins the split of the country into a northern kingdom of Isin and a southern kingdom of Larsa. The two dynasties existed side by side for over two centuries, until the last ruler of Larsa, Rim-Sin, conquered Isin, thus uniting the greater part of the country. He in turn was defeated (*c.* 1770) by King Hammurabi of Babylon, who thereby became the first after the 3rd dynasty of Ur to reunite the whole country.

During the Isin-Larsa period several changes took place. First, the Akkadian language gradually won out over the Sumerian; Sumerian henceforth was learned only in the schools and used for religious purposes. Second, the statist system of the 3rd dynasty of Ur was replaced by an economic system based on private enterprise. Documents of the period found at Ur show how overseas trade was financed by private capital. Third, a new wave of Semites appeared in Babylonia. Their language is known mainly from proper names; for writing they used the Akkadian language only. Their native idiom is of western Semitic type, akin to Canaanite. Scholars use various names for these newcomers, that most commonly applied being Amorites, based on the assumption that the Akkadian term *Amurrû*, which means "westerner," refers to these people (*see* Amorites). Other scholars reject the attribution of *Amurrû* to this group, taking *Amurrû* as a general term for "nomads," and call the newcomers (Eastern) Canaanites or simply western Semites. Individuals bearing names of this type first appear in Larsa, where they soon seized the throne, and a little later also in Sippar. In the north of the alluvial plain these newcomers established a dynasty of their own at Babylon, which now for the first time plays a political role. The establishment of this dynasty of Babylon and the simultaneous appearance of western Semites in Larsa can be dated approximately to 1900 B.C. From then on, the three dynasties of Babylon, Isin and Larsa coexisted for about a century until their final fusion.

2. Eshnunna and Ashur.—With the downfall of the empire of Ur, the Diyala region, or Eshnunna, became a kingdom under independent rulers. Farther north on the Tigris, Ashur now emerges from the dawn of prehistory. The Assyrian king list, now complete, begins with 30 rulers of whom there is no other knowledge; it is probable that some of these names belong to the Bedouin ancestors of the usurper Shamshi-Adad (*see* below) rather than to kings of Assyria proper. With king no. 31, Ilu-shuma, authentic royal inscriptions begin. Under his successors, Assyrian merchants founded trade colonies in Anatolia. They exported tin and textiles to Anatolia, organized some of the local copper trade there and brought home silver—that is, cash. The centre of these colonies was Kanesh, the mound called Kültepe near Kayseri (Caesarea Mazaca) in Turkey, but there were smaller settlements in many other places. The colonies lasted for some 70 years; part of this period fell into the reign of Sharrum-kin I of Assyria, the 35th king according to the Assyrian king list. King no. 37 bears the same name as a ruler of Eshnunna, Naramsin; identity of the two seems likely, whether Eshnunna ruled over Ashur or vice versa. The 38th king was dethroned by a usurper, a western Semite by the name of Shamshi-Adad, who seems to have come from Terqa on the middle Euphrates and, after a sojourn in Babylon, where the dynasty was of the same ethnic stock, conquered Ashur and became its 39th king (*c.* 1820). Even before he had seized the throne, he conquered Mari on the middle Euphrates, with whose rulers he had an old feud. After his accession he installed his second son, Yasmakh-Adad, as viceroy in Mari. Although Shamshi-Adad built temples in Ashur, he mostly resided in a new capital, Shubat-Enlil, probably to be identified with Tell Chagar Bazar in the Khabur region, where texts pertaining to his reign have been found.

3. Old Babylonian Period.—Toward the end of the Isin-Larsa period the kingdom of Larsa was conquered by a certain Kudur-Mabug, a man with an Elamite name who ruled in Yamutbal east of the Tigris. He installed as king in Larsa his son Warad-Sin, who was succeeded by his brother Rim-Sin. Rim-Sin, by uniting the former kingdoms of Isin and Larsa under his rule, became the rival of Hammurabi of Babylon, who came to the throne *c.* 1800 or about 20 years after Shamshi-Adad.

Hammurabi's kingdom thus was surrounded by powerful neighbours: Rim-Sin, Shamshi-Adad and the king of Eshnunna. Shamshi-Adad died shortly after the tenth year of Hammurabi, and after his death Assyria suffered a setback that of course was to the advantage of Hammurabi. Yasmakh-Adad was driven out

of Mari by Zimri-Lim, the son of the last local ruler before Shamshi-Adad, who had found refuge in Aleppo and now returned to his ancestral throne. The royal archives of Zimri-Lim of Mari are the main sources for the political history of the time. Zimri-Lim at times enjoyed the help of Hammurabi, who used him as a pawn in his political game. Shamshi-Adad's oldest son, Ishme-Dagan, his successor on the throne of Assyria (king no. 40), also seems to have suffered defeat from various neighbours. Hammurabi helped him on some occasions, but, from the fact that he claimed rule over Ashur toward the end of his reign, it seems that Hammurabi held some kind of suzerainty over Ishme-Dagan, at least in the end. Toward Eshnunna, too, Hammurabi's policy varied according to circumstances; it finally led to the conquest of that country. In his 30th year (*c.* 1770) Hammurabi was strong enough to defeat Rim-Sin of Larsa. Several years later he probably took Mari, putting an end to Zimri-Lim's independent rule. For the last decade of his 43-year reign, then, Hammurabi ruled over a kingdom that extended from the Persian gulf to Mari and Ashur and eastward to the Zagros mountains.

The reign of Hammurabi was the classical age of Old Babylonian civilization. From his correspondence one gets the impression of a shrewd politician and a good administrator who took pains to further the welfare of his subjects. Letters to his governors contain detailed instructions for the enforcement of justice and order. Most famous is his law code, composed in his later years. It was inscribed on a diorite stele discovered in Susa, where the Elamites carried it at a later date. Contemporary and later copies on clay tablets also exist.

Hammurabi's law was not the first codification known from ancient Mesopotamia. Fragments of a Sumerian code of King Ur-Nammu of Ur were found, also a Sumerian law code of King Lipit-Ishtar of Isin. Whereas these Sumerian laws antedate Hammurabi by 350 and 150 years, respectively, there is one in Akkadian from Eshnunna which is only about 50 years older than the famous code of Hammurabi.

A great number of legal and economic documents of the period give a lively picture of its life. The economy, as in the Isin-Larsa period, was based on private property and enterprise, and trade was flourishing. Of Hammurabi's buildings in Babylon itself nothing can be excavated because they are below ground-water level, but living quarters with private dwellings were found at Ur, and the palace of Zimri-Lim at Mari shows the high living standards of a ruler of the time.

With the rise of Babylon to the capital of a large united kingdom, its city-god Marduk became supreme, replacing the Sumerian god Enlil as head of the pantheon. Literature flourished in this classical period. The Akkadian language of this age, called Old Babylonian, was developed into a literary language in which many of the great epics and hymns were composed, among them the *Epic of Creation* which gave the mythological justification for Marduk's rise to power (*see* Creation, Myths of). Sumerian literature, too, was studied and copied in the schools; in fact almost all extant copies of Sumerian literary works were written in the Old Babylonian period, although the texts must have been composed earlier, when Sumerian was still a living language. Representative art of the period excels by quality more than by inventiveness; yet the glyptic art of the Old Babylonian period influenced that of Syria in the centuries to come.

After Hammurabi, his dynasty continued in unbroken father-son sequence for five generations: Samsu-iluna (38 years), Abi-eshukh (28 years), Ammi-ditana (37 years), Ammi-saduqa (21 years) and Samsu-ditana (31 years). These kings were not able to maintain Hammurabi's empire, although cultural and economic life went on in Babylonia along the lines developed under him. Under Samsu-iluna the region next to the Persian gulf broke away and became an independent kingdom called the Sea Land under a dynasty that tried to revive Sumerian tradition. Ashur regained independence, and in the north new peoples arose that threatened Babylonia. Then, 155 years after the death of Hammurabi, the 1st dynasty of Babylon was destroyed by an invasion of new peoples (*c.* 1600 B.C., according to the chronological system adopted here).

D. Middle Period

1. Hittites, Hurrians and Kassites.—The downfall of the 1st Babylonian dynasty is mentioned in a later chronicle with the following laconic sentence: "At the time of Samsu-ditana the Hittite went to the land of Akkad." A Hittite record reads: "He [*i.e.*, the Hittite king Mursili I] went to Aleppo and destroyed Aleppo and brought captives and goods of Aleppo to Hattusa [or Khattushash, the Hittite capital]. But afterward he went to Babylon and destroyed Babylon. Also the Hurrians he defeated, and he kept captives and goods of Babylon in Hattusa." These two sources, which obviously refer to the same event, mention two of the new peoples that appeared on the scene: the Hittites (*q.v.*), who had established a kingdom in central Anatolia two generations before the sack of Babylon; and the Hurrians (*q.v.*), whom Mursili obviously had to defeat in order to keep his Babylonian booty, and who are found throughout the 2nd millennium in north Syria and north Mesopotamia. The language of the Hittites belongs to the Indo-European family of languages, whereas the Hurrian language is not related to any known linguistic group. Though Hurrians are known from earlier times, the latter part of the 1st dynasty of Babylon is the first time they play a role on the political scene. But these are not the only new ethnic elements.

According to the Babylonian king list the dynasty following the 1st Babylonian is that of the Kassites (*q.v.*). The Kassites spoke another language that is neither Indo-European nor Semitic; it is assumed that they came from east of the Tigris. Hammurabi's son, Samsu-iluna, had to fight them, and under his successors they are mentioned again. During the two generations preceding the fall of Babylon, Kassites were in control of Hana on the middle Euphrates. The question as to whether the Kassites established their rule over part of Babylonia even before the fall of Babylon, so that the 1st Babylonian and Kassite dynasties would overlap, is still debated and is closely connected with chronological problems.

2. Chronology.—Until the 1930s a chronological system had seemed fairly well established. Then it was learned from the Mari letters that Hammurabi of Babylon was a contemporary of Shamshi-Adad of Assyria, who had been believed to have reigned about a century later than Hammurabi. At about that time an almost complete copy of the Assyrian king list was discovered by the Oriental institute expedition at Khorsabad. Since then, some scholars (W. F. Albright and most German scholars) have essentially followed the Assyrian king list, according to which Shamshi-Adad would have ruled around 1700 B.C. and the Babylonian kings from Hammurabi to the end of his dynasty would cover the period from *c.* 1700 to shortly before 1500. This contradicts the statement of the Babylonian king list, which attributes 576 years to the Kassite dynasty: since its end is fixed to 1160 B.C., that dynasty would have begun in 1736; *i.e.*, before the new date proposed for Hammurabi.

Several solutions of the problem have been proposed: reduction of the Kassite dynasty to less than 576 years, overlap of the two dynasties and a combination of the two. Astronomical observations of the heliacal rising of the planet Venus for the reign of Ammi-saduqa exist in a later copy, but since the rising of Venus repeats itself in a cycle of 56 or 64 years, these observations fit several dates and can be used only if other considerations point to a particular span of time. Some of the various solutions offered are these: F. Thureau-Dangin, immediately after the Mari discoveries, chose a Venus period according to which the fall of Babylon would be dated *c.* 1660; this was taken up in the 1950s by A. Goetze. Sidney Smith decided for the next Venus period, which puts the fall of Babylon to 1596, and this chronology has been adopted here. B. Landsberger showed that the Assyrian king list omits some kings known from other sources, so that figures based on it are demonstrably too low. He also drew attention to the fact that the period following the fall of Babylon was a dark age indeed, and that at the time when sources begin to speak again, *c.* 1500, the near east had undergone such changes that a chronology placing the fall of Babylon only a short time before 1500 B.C. (Albright) would not leave enough time for these changes to take place. Landsberger's main point is that a definite solution is impossible with the material available. Concerning the Kassites,

he avoids the overlap by slightly reducing the figure 576 and by dating the fall of Babylon around 1700. Sidney Smith accepts an overlap, since 1736 for him falls into the reign of Samsu-iluna who defeated the Kassites. Albright's system presupposes both overlap and reduction of the 576 years. (*See* also CHRONOLOGY.)

3. Feudal Age.—The new era is characterized by the appearance in most near eastern countries of a feudal system based upon an aristocracy of chariot warriors. It is found in the Hittite kingdom of Anatolia, in Syria and north Mesopotamia and in Kassite Babylonia. Most of the area settled by Hurrians was organized under the rule of an Aryan dynasty in a kingdom called Mitanni. The Mitanni, in contrast with the Hurrian population, spoke a language, known from ancient India, which was a precursor of classical Sanskrit; presumably the Mitanni represent one branch of those Aryan tribes the bulk of which finally reached India. These Aryans have been credited with the introduction of the horse-drawn light war chariot, but the evidence is insufficient. It comes from a handbook for the training of horses, found in the Hittite capital and written in Hittite, which is the work of a Mitanni and contains technical terms both in Hurrian and in the Indo-Aryan language. Whoever may have introduced the new instrument of warfare, the fact is that by 1500 it was in general use in the countries just mentioned. An Assyrian handbook of hippology and Kassite lists of chariot horses belong to the same general period.

The Mitanni kingdom included at least part of Assyria, reaching as it did to Kirkuk in the east. It is assumed that some of the Assyrian kings of the 15th century were under the overlordship of the kings of Mitanni, although the king list does not mention such a foreign rule but rather gives an uninterrupted sequence of kings of Ashur.

In Babylonia the first inscriptions after the dark age begin with the 16th Kassite king, Karaindash, *c.* 1450 B.C. Administrative documents first appear under the 20th king, Burnaburiash II. who was contemporary with Pharaoh Amenhotep IV (Ikhnaton), *c.* 1360 B.C. The correspondence of this Pharaoh, found at Tell el Amarna in Egypt, shows a system of great powers, whose rulers bear the title of "Great King" and address one another as "My Brother." These are Egypt, Mitanni, the Hittite kingdom, Babylonia and, in fact, though not at first formally recognized, Assyria. The Assyrian king of the Amarna age was Ashur-uballit I, who, together with the Hittites, annihilated the kingdom of Mitanni and thus established Assyrian rule in northern Mesopotamia again.

4. First Assyrian Empire.—The centuries following the Amarna age are characterized by the rivalry of Assyria and Babylonia. During the period from Ashur-uballit I (*c.* 1360) to about 1200 B.C. Assyria was the more powerful of the two. Ashur-uballit himself played an active role in Babylonian politics. He married his daughter to the Kassite king and later, when the son of this daughter was removed by a local rival, installed another Kassite prince, Kurigalzu II, on the throne. During the 13th century the throne of Assyria was held by three powerful kings: Adad-nirari I (1308–1275), Shalmaneser I (Shulman-asharid, 1275–45) and Tukulti-Ninurta I (1245–08). First Adad-nirari and after him again Shalmaneser conquered the western part of north Mesopotamia, which, after the destruction of the Mitanni kingdom, had been under Hittite domination.

All three kings led successful campaigns into the Zagros mountains east of Assyria, and the last two also into Armenia. Adad-nirari claims a victory over the Kassites of Babylonia; a decisive victory was won by Tukulti-Ninurta over the Kassite king Kashtiliash III, an event that became the subject of an epic poem.

Kashtiliash was taken prisoner, Babylonia was conquered and apparently ruled by Tukulti-Ninurta himself. Several years later, however, Babylonia regained its independence, and Tukulti-Ninurta's last years seem to be overshadowed by his own growing restlessness. At first he built a new palace in Ashur itself. Later he founded a new capital, across the Tigris from Ashur, which he called Kar-Tukulti-Ninurta. Finally he was killed by his own son. About the causes of this development it is possible only to speculate.

5. Relation of Assyria to Babylonia.—Both Assyrians and Babylonians spoke the same language, Akkadian, but two different dialects of it, which scholars call Assyrian and Babylonian, respectively. Higher civilization developed in Babylonia. Religious beliefs were essentially the same in both countries, except that in Assyria the city-god of Ashur, the god Ashur, was supreme instead of the Sumerian Enlil or Marduk of Babylon. As a literary language the Assyrians wrote Babylonian; the Assyrian dialect was used mainly for private documents and other nonliterary works, such as the Assyrian laws, extant copies of which date from *c.* 1100 B.C. In art, Assyria went its own way; this is evident from the cylinder seals of the Middle Assyrian period (14th to 12th centuries) and becomes even more striking with the emergence, in the 9th century, of an Assyrian relief art that has no equal in Babylonia.

About the reasons for the difference between Assyrians and Babylonians it is possible only to speculate. Different ethnic substrates or admixtures have been adduced, but the role they may have played in shaping the two nations is hard to define. For some periods there is evidence of a difference of attitude toward Babylonia prevailing in different circles or factions among the Assyrians: pro-Babylonian and anti-Babylonian. That such difference of opinion may have existed at the time of Tukulti-Ninurta has been suggested as a possible explanation for his assassination.

After the death of Tukulti-Ninurta, Assyrian power declined, while that of Babylonia rose. Around 1135 a Babylonian king was able to determine the policies of Assyria. A short time later, Nabu-kudurri-usur I reigned, a powerful Babylonian king who was successful against Elam in particular. But during his last years there arose in Assyria a new ruler, Tiglath-pileser I (Tukulti-apal-Esharra; 1116–1076), who brought Assyria back to the status it had had in the 13th century. He fought successfully against the Nairi countries (Armenia) and against such formerly Hittite places as Malatya (Milid) and Carchemish on the Euphrates (the great Hittite empire of the 14th and 13th centuries had been swept away in the Aegean migrations of *c.* 1180 B.C.); near the upper Euphrates he also defeated the Mushki, a people said to have arrived there 50 years before his time (*c.* 1165), possibly one of the tribes that came into Anatolia in connection with those migrations. In the Syrian steppe he defeated Aramaean tribes (this name appears here for the first time), and he even reached the coast of northern Syria. Later Tiglath-pileser conquered northern Babylonia, including the city of Babylon, but left it under its local king.

After Tiglath-pileser I, Assyrian power declined again, while Babylonia, too, was in a state of insignificance. The most important element in the west was now the Aramaeans, who established themselves in many of the formerly Hittite states of north Syria, founded a powerful kingdom with Damascus as capital, settled in lower Babylonia near the Persian gulf and also pressed against the borders of Assyria proper.

6. New Rise of Assyria.—Under Ashur-dan II (933–910), Adad-nirari II (910–889) and Tukulti-Ninurta II (889–884), we hear again of Assyrian successes, mainly near the border and against such Aramaean states as Laqe on the middle Euphrates. The following two kings, Ashurnasirpal II and Shalmaneser III, then led Assyria to a new expansion.

Ashurnasirpal (Ashur-nasir-apli II; 884–859) is known for the cruelty with which he conducted his wars. Enemies were impaled, flayed or beheaded in great numbers. He succeeded in subjugating the Aramaean tribes of Mesopotamia and in incorporating their territories into his kingdom. He undertook a campaign to the Mediterranean coast during which he received tribute from the Late Hittite kinglets of north Syria as well as from the Phoenician cities. Other campaigns were directed north into the Nairi countries and east into the Zagros mountains.

Ashurnasirpal built a new capital in Kalakh (modern Nimrud on the Tigris south of Nineveh), a town founded by Shalmaneser I but later abandoned. His palace was among the first monuments discovered in the 1840s and was re-excavated in the 1950s. It is the earliest Assyrian building known that is decorated with reliefs on wall slabs, the first example of the great Assyrian relief art that flourished from then on to the end of the empire in the 7th

century. (*See* also Ashurnasirpal.)

Shalmaneser (Shulman-Asharid III; 859–824) kept and enlarged his father's empire. He conquered the Aramaean kingdom of Bit-Adini and turned its capital, Til Barsib (Tell Ahmar on the Euphrates), into an Assyrian stronghold and centre of a province. In Syria he met a strong coalition led by Bar-Hadad I (biblical Ben-Hadad; throne name, Hadadezer; Akkadian, Adad-idri) of Damascus and including King Ahab of Israel. The battle of Karkar seems not to have been a victory for the Assyrians, for their army returned to Kalakh and did not come back to Syria for the next few years. Not until after the death of Ahab and Bar-Hadad was Shalmaneser able to reach his goal. Damascus was besieged, though not conquered, and its oasis was devastated. Most Syrian rulers paid tribute, among them Jehu of Israel, as depicted on Shalmaneser's obelisk. Shalmaneser then turned toward the north, where he reached the source of the Tigris. This event, together with other campaigns, is depicted on bronze bands found at Balawat (see *Archaeology, Architecture and Art,* above).

In Armenia, the region previously known as the Nairi lands, a unified kingdom under the name of Urartu (*q.v.;* biblical Ararat) emerged by this time. It remained Assyria's most active rival for the centuries to come. The kings of Urartu left inscriptions in cuneiform writing, borrowed from Assyria, in the local language (called variously by scholars Urartaean, Vannic—from the capital, modern Van in Turkey—or Khaldic), which is related to Hurrian and may be a late stage of a dialect of that language.

In Babylonia the struggle of two contestants for the throne gave Shalmaneser an opportunity to appear with his army. While in Babylon itself he contented himself with reinstituting the rightful king and making offerings to the gods; he conducted a campaign against the Aramaeans who had settled in the region near the Persian gulf, the ancient Sea Land. These south Babylonian Aramaeans, also known as Chaldeans, among them the leading tribe of Bit-Yakin, were made tributary (*see* Aramaeans; Chaldea).

Toward the end of Shalmaneser's reign there was a general revolt against him led by his eldest son. His second son, who remained loyal, succeeded him as Shamshi-Adad V (824–810) and suppressed the rebellion with the aid of the Babylonians. Under Shamshi-Adad V, the Medes of Iran are mentioned for the first time in history. After his death his widow, Sammu-ramat, known to posterity under her Graecized name Semiramis, was regent for her son Adad-nirari III (810–782) during the five years before he came of age. Under the successors of Adad-nirari III, Assyrian power suffered another setback. Inscriptions of some provincial governors of the period bespeak a decline of the royal authority. The final rise of the New Assyrian empire only came with Tiglath-pileser III.

E. Late Period

1. New Assyrian Empire.—Tukulti-apal-Esharra III (745–727), the biblical Tiglath-pileser, was a general who usurped the throne. He succeeded in establishing a real empire reaching from the Persian gulf to the Armenian mountains and including all of Syria and Palestine to the Egyptian border. By breaking up large provinces into smaller units and by the systematic deportation of the population of conquered territories—a measure already applied by earlier Assyrian kings—he established a strong centralized administration of the vast empire. Among his numerous campaigns the most important are described below.

King Sardur II of Urartu, who led a coalition of north Syrian rulers against the Assyrians, was defeated in Commagene and had to flee to his capital, Tushpa (Van). Though Tiglath-pileser was unable to conquer this fortress, he included the southern part of Armenia in his empire and severely punished Sardur's north Syrian allies. All Syrian states either submitted or were defeated. Several Israelite kings paid tribute (II Kings xv, xvi), and Damascus and Gaza were conquered.

Babylonia at first acknowledged the supremacy of Ashur. Revolts and dynastic struggles after the death of King Nabu-nasir (Nabonassar; 747–735) finally led Tiglath-pileser in 730 to a campaign into Babylonia, during which he defeated several Aramaean tribes and received their tribute; the Chaldean Marduk-apal-iddina (Merodach-baladan) was one of their tribal chiefs. In Babylon itself Tiglath-pileser "seized the hands of Marduk" and made himself king of Babylon under the name of Pulu (biblical Pul), thus for the first time uniting the two kingdoms of Assyria and Babylonia in a personal union. (*See* also Tiglath-pileser.)

His son Shalmaneser V (727–722) continued the same policy; his Babylonian throne name was Ululai. The most renowned event of his reign is the revolt of Hosea of Israel, which led to the siege of Samaria by Shalmaneser. He was removed, however, by a military revolt that brought another usurper to the throne: Sharru-kin II, the biblical Sargon.

The conquest of Samaria is attributed to Shalmaneser V in the Bible, whereas Sargon claims it as his own success during his accession year; the question is still debated. The deportation of the ten tribes of the northern kingdom is the best-known example of an old Assyrian policy.

Sargon.—With Sargon II (722–705) begins the last dynasty of Assyria, often referred to as the Sargonids, a sequence of four exceptionally gifted kings under whom the empire reached its peak. Apart from the annals of the kings and the relevant parts of the Babylonian Chronicle, an important source for the history of the period are the state letters found at Nineveh, which also give a lively picture of the administration and the cultural life.

Sargon fought many wars in order to maintain and enlarge the empire of his predecessors. In Palestine, where the northern kingdom became an Assyrian province, the southern kingdom of Judah under King Hezekiah maintained its existence by paying tribute. The Philistine towns of Gaza, Ashdod and Gath were put under Assyrian administration after an attempt of Hanun of Gaza to re-establish himself in his home town with Egyptian help had failed. Several revolts in the rest of Syria and southeastern Anatolia were put down by Sargon, who finally abandoned the policy of taking tribute from local rulers and rather turned their territories into Assyrian provinces. This was the end of the Late Hittite and Aramaean states of the region. Tabal (around Kayseri in Turkey) and Kue (the Cilician plain) became the westernmost provinces. King Midas of Phrygia, called Mita of Mushki by Sargon, was prevented from taking Cilicia and had to pay tribute, but was able to maintain his independence. Greek cities in Cyprus, where a stele of Sargon was found, acknowledged the supremacy of the Assyrian king. Urartu, weakened by attacks of the Cimmerians, who had come across the Caucasus, could not withstand Sargon's attack. In 714 Tushpa was conquered, King Rusa committed suicide, a rich booty was taken to Assyria and Rusa's successor, Argisti II, who kept only a small part of Urartu, became an ally of Assyria.

In Babylonia the Chaldean Merodach-baladan had made himself king early in Sargon's reign and secured the help of Elam. An attempt of Sargon, in his second year, to bring Babylonia under his control failed; he was defeated by the Elamites, and Merodach-baladan remained king for ten more years. Not until his 12th year (710) was Sargon able to defeat Merodach-baladan, who fled to Elam; the Chaldean tribes were punished, but in Babylonia proper Sargon took the role of a restorator. He called himself "king of Sumer and Akkad" but only "governor" of Babylon; he celebrated the New Year festival in Babylon and did much for the rebuilding of Babylon and other Babylonian towns.

In Assyria, Sargon first resided at Kalakh, but in 713 he began to build a new residence for himself, Dur-Sharrukin, "Sargon's fortress" (Khorsabad, northeast of Nineveh), where his palace with many reliefs and inscriptions has been excavated. Sargon lost his life on a campaign in Iran in 705 and was succeeded by his son Sennacherib. (*See* also Sargon.)

Sennacherib.—Sennacherib (Sin-akhkhe-eriba; 705–681) differed from his father in many respects, especially in his attitude toward Babylonia. He immediately abandoned Dur-Sharrukin and resided first in Ashur and later in Nineveh, where he built a palace and which from then on remained the real capital of Assyria. In Babylonia Merodach-baladan seized power again in 703 with the help of Elam. But only nine months later Sennacherib defeated the coalition of Elamites, Babylonians and Chaldeans;

Merodach-baladan fled again, and Sennacherib put a man of his choice on the throne of Babylonia. In the meantime, Hezekiah of Judah revolted, instigated by Merodach-baladan and the king of Egypt. In 701 Sennacherib marched into Palestine, where he conquered Lakhish (Lachish) and besieged Jerusalem. Both the Bible (II Kings xviii, 13–xix, 36; II Chron. xxxii, 1–22; Isaiah xxxvi, 1–xxxvii, 37) and Herodotus have kept the memory of how he had to give up this siege; in spite of this retreat, which was considered a miracle, Hezekiah paid tribute and thus saved his kingdom for the future.

The ill fate of the siege of Jerusalem was the signal for the Babylonians to revolt again. Sennacherib, in 700, suppressed this revolt and installed his own son Ashur-nadin-shum as king of Babylon. He then decided to punish the Elamites for the help they had given the Babylonian insurgents. For this purpose he had ships built in Syria and Assyria, which were manned with Phoenician and Ionian sailors and sailed down the Euphrates and Tigris for an attack on Elam from the Persian gulf. In 694 he landed in Elam and looted several towns, but in his rear the Elamites occupied Babylonia, captured Ashur-nadin-shum and put a man of their choice on the throne. The war went on for the following years with varying success; finally in 689 Sennacherib conquered Babylon, where a Chaldean, Mushezib-Marduk, was then king, and punished the city severely. The statue of the god Marduk was taken to Ashur, the city itself was looted and completely destroyed, even flooded by a diversion of the river. For the rest of Sennacherib's reign the city of Babylon remained a wasteland.

Sennacherib's palace in Nineveh, like the palaces of his predecessors, was adorned with reliefs. They show a considerable advance in the lively rendering of landscape and of crowded scenes. Among the latter there are pictures of the transport of huge bull colossi. The engineering skill of the period also is reflected in an aqueduct by which fresh water for the capital was led across a valley near Jerwan. In Ashur, to which the New Year festival was now transferred, trees for the garden of the new festival house were planted on a rocky plateau in holes cut into the rock and filled with earth.

The destruction of Babylon was considered by many a grave sin. In 681 Sennacherib was killed by some of his sons. The details of the event and its causes are debated, especially the question of whether his successor, who was a younger son, was involved in the plot. (*See* also SENNACHERIB.)

Esarhaddon.—At any rate, Esarhaddon (Ashur-akh-iddina; 681–669), who followed his father on the throne, represented the pro-Babylonian faction; he immediately began to rebuild Babylon and did much for the restoration of temples also in other Babylonian cities. Like Sargon he used only the title of "governor of Babylon" for himself.

In the north, the Cimmerians became more and more a menace. Another Asian people, the Scythians (Assyrian Ishkuza), appeared in the same region. Numerous oracle questions by which Esarhaddon tried to find out what these people would do show the degree to which he felt this danger; they betray a weakness that contrasts with the king's military success in other parts. In order to secure help against the Cimmerians, he even gave his own daughter as a wife to Bartatua, king of the Scythians (Herodotus renders the name as Protothyas).

Esarhaddon extended the empire farther than any Assyrian king before him by conquering Egypt. A first campaign of 673 failed. After careful preparations, another Assyrian army went out in 671. This time the Egyptians under the Ethiopian king Taharqa (Tarku, biblical Tirhakah) were defeated, Memphis, the northern capital, was taken and the land was organized in 22 districts under local rulers, each of them under the supervision of an Assyrian governor. However, revolts followed soon, both in Egypt and in Assyria. After having restored order at home, Esarhaddon set out himself to suppress the Egyptian revolt but died on the way. (*See* also ESARHADDON.)

Ashurbanipal.—Esarhaddon had designated a younger son of his, Ashurbanipal (Ashur-bani-apli), as his successor on the throne of Assyria, while his elder son, Shamash-shum-ukin, was to become king of Babylon under Ashurbanipal's overlordship. Although this decision, in which the dowager queen Nakiya (whom some believe to be the Nitokris of Greek tradition) had played a role, met with some criticism, it was accepted, and after Esarhaddon's death his two sons succeeded him as ordered.

Ashurbanipal (669–630) had an excellent education. Not only was he well trained in warfare and all manly sports but he also learned to read and write cuneiform, to read even old Sumerian texts and to solve mathematical problems. His interest in literature was a very real one as his creation of a library shows.

At the beginning of Ashurbanipal's reign the Egyptian revolt was suppressed by the general who led the army after Esarhaddon's death. The Ethiopian king Taharqa fled; the Egyptian Necho I was taken prisoner and later installed in Egypt as an Assyrian vassal, while his son Psamtik was given a province. In 664, however, a new revolt broke out, which was suppressed once more. On this occasion Thebes, the capital of Upper Egypt, was destroyed and obelisks were brought to Nineveh. All this did not secure a permanent rule. Around 655 Psamtik I was able to drive out the Assyrians and to establish a new, independent Egyptian kingdom, known as the Saite dynasty. He received help from Gyges of Lydia (Guggu, king of Luddu, in Assyrian), who sent him Carian and Ionian mercenaries. Several years earlier, Gyges had offered Ashurbanipal his alliance against the Cimmerians. When in 652 Gyges was killed in a new attack of the Cimmerians, Ashurbanipal considered this the punishment for the role he had played in Psamtik's insurrection.

In the same year, 652, Shamash-shum-ukin of Babylon revolted, having secured the help of Psamtik, the Elamites and Aramaean and Arab tribes. After four years of fighting Ashurbanipal conquered Babylon in 648; Shamash-shum-ukin died in the conflagration, and a man by the name of Kandalanu was made king of Babylon. Ashurbanipal then proceeded against Elam, which had caused so much trouble in Babylonia.

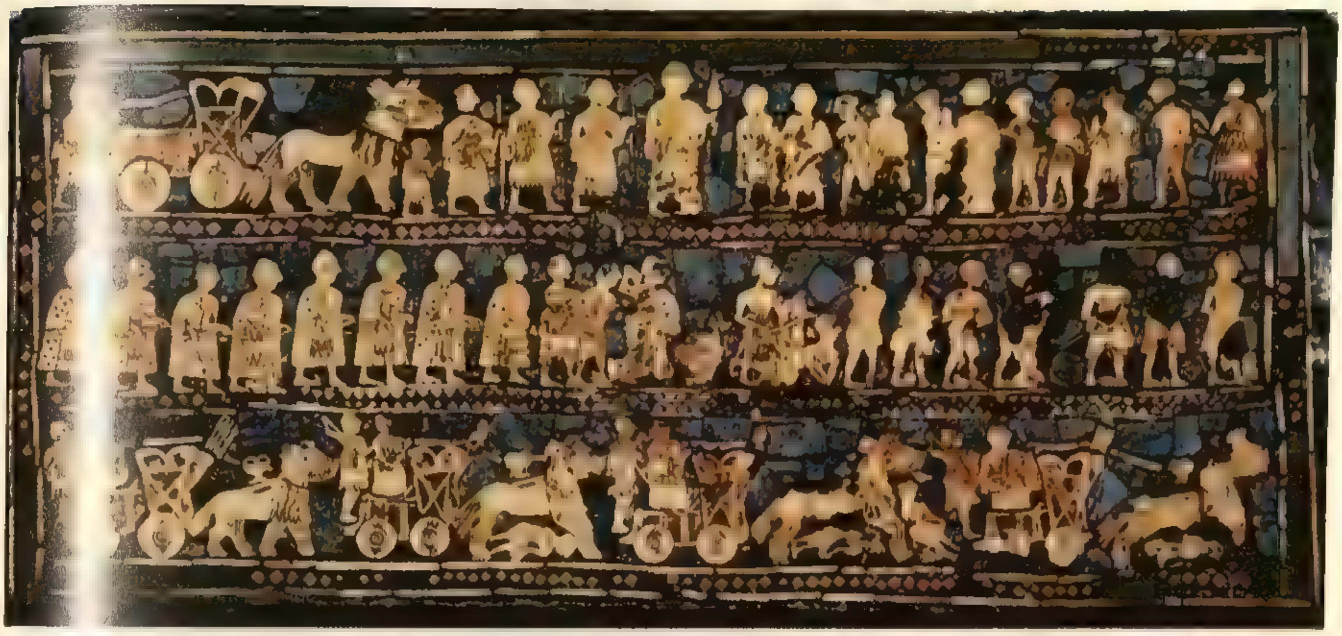
After a long war Elam was finally conquered and its capital, Susa, destroyed in 639. Ashurbanipal also fought against the Arabs who had helped Shamash-shum-ukin. Of the last years of his reign little is known; we hear only that Cyrus I of Persia, the grandfather of Cyrus the Great, once sought an alliance with Ashurbanipal, probably against the Medes.

Ashurbanipal's palace in Nineveh was decorated with elaborate reliefs that show the highest degree of artistic achievement. Especially the pictures of lions and other animals in the numerous hunting scenes are masterpieces. The victories over the camel-riding Arabs and over Elam are the subjects of other relief series, and even the hunting and garden scenes contain allusions to the king's victory over Elam.

The creation of Ashurbanipal that became most important for posterity was his library. All works of Babylonian literature were collected there in very careful copies made of originals that the king's emissaries found in Babylonian schools. That this library was discovered in one of the mounds of Nineveh as early as the 1840s was most fortunate. (*See* also ASHURBANIPAL.)

2. End of Assyria.—Ashurbanipal was succeeded by his sons Ashur-etil-ilani (*c.* 630–627) and Sin-shar-ishkun (627–612), about whom little is known. In Babylonia Kandalanu, who had been installed there by Ashurbanipal, continued on the throne until 627. After his death there was anarchy in Babylonia; Sin-shar-ishkun tried to gain control and had temporary success in part of the country, as evidenced by contracts dated according to his reign in Nippur. He was opposed by a Chaldean, Nabu-apal-usur (Nabopolassar), who was able to establish himself as king in 626 and to conquer Babylon a little later. The following years were filled with wars between Assyria and the Chaldean king, during which border regions were taken and retaken. A new enemy of Assyria was the Medes under King Cyaxares (Umakishtar in Akkadian), who came to the throne about 624. Around 620 Sin-shar-ishkun had a success against Cyaxares, but soon the war entered its final stage.

With the year 616 there begins a part of the Babylonian Chronicle that deals with the events leading to the fall of Nineveh. In that year Nabopolassar marched up the Euphrates and Khabur

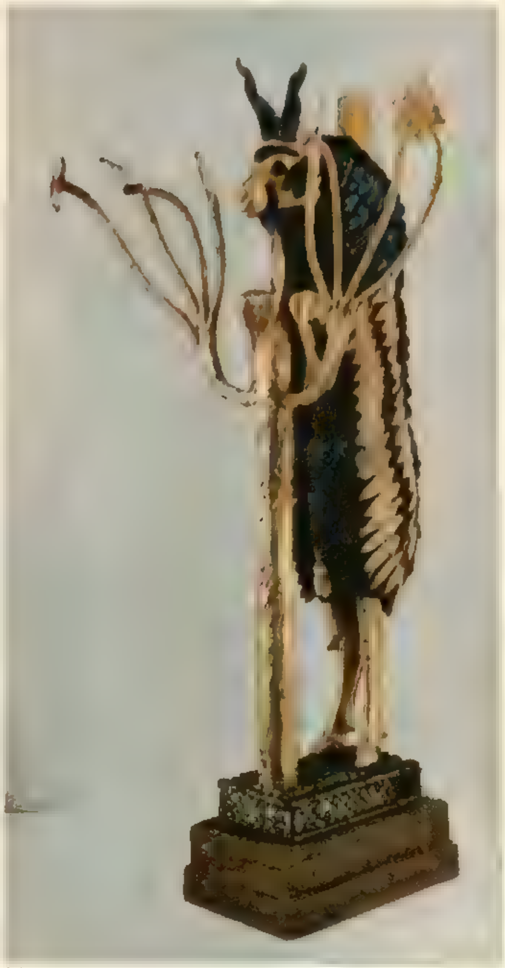


Inlaid standard showing battle and victory scene, a mosaic made of lapis lazuli, shell, coloured stones and mother-of-pearl. The reverse side depicts gift-bearers and banqueting scenes. From Ur, Early Dynastic III period

MOSAIC WORK, PAINTING, RELIEF AND METALWORK OF ANCIENT BABYLONIA AND ASSYRIA

Adoration scene from painted plaster panel found at Khorsabad (Dur-Sharrukin), representing Sargon II and (perhaps) a minister before the god Ashur. New Assyrian period

Figure of a rampant goat, made of gold and silver, lapis lazuli, red sandstone and shell, from a royal tomb at Ur. One of a pair. Height: 18½ in. Early Dynastic III period



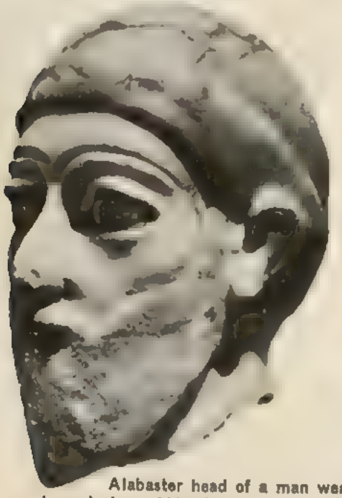
Lion relief in glazed brick, panel from wall-lined street leading from Ishtar gate to temple of Marduk, Babylon; built in reign of Nebuchadrezzar II, 605–562 B.C., Neo-Babylonian period

BABYLONIA AND ASSYRIA

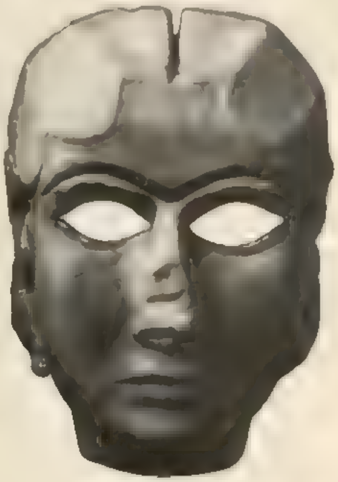
Seated female figure, terra cotta; Tell Halaf period. From Tepe Gawra

Stone statuette; Protoliterate period. From the temple of the moon-god, Sin, IV Khafajah

Inscribed statue of Puzur-Ishtar, governor of Mari, found at Babylon. Ur III period, c. 2000 B.C.



Alabaster head of a man wearing a turban; Akkadian period; c. 24th century B.C. From Adab (modern Bismayah)



One of the earliest examples of true sculpture in the round, an incomplete head from Warka (Uruk). Protoliterate period

Alabaster statue of a priest; Early Dynastic II period. From the temple of Abu at Eshnunna (Tell Asmar)

Statue of Gudea in the traditional pose of reverence; 22nd century B.C. From Lagash (modern Telloh)

Votive statue of turbaned Gudea made of diorite; 22nd century B.C. From Lagash (modern Telloh)

BABYLONIAN AND ASSYRIAN SCULPTURE IN THE ROUND

Copper goat's head from Shuruppak (modern Tell Fa'rah); Early Dynastic period

Copper statuette of nude male carrying a box on his head; Early Dynastic period

Statuette of Ur-Nammu, 3rd dynasty of Ur, shown carrying a basket. From Nippur, c. 2100 B.C.

Two-wheeled copper chariot from the Shara temple, Tell Agrab; Early Dynastic II period

Front view of bronze head, considered by some authorities to be Sargon I of Agade; from Nineveh; Akkadian period, second half of 3rd millennium B.C.

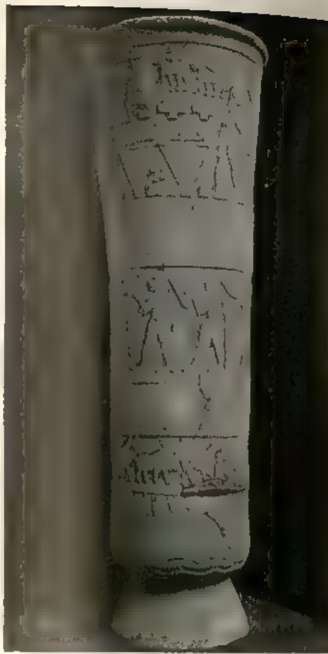
Silver vase of En-temena, king of Lagash, engraved with representation of Imdugud attacking lions; Early Dynastic III period. From Telloh

Double copper vase supported by a pair of wrestlers, from the Nintu temple, Khafajah; Early Dynastic II period

BABYLONIAN AND ASSYRIAN METALWORK

BABYLONIA AND ASSYRIA

Representation of lion-headed bird Imdugud and two stags, a copper relief from El 'Ubaid which combines bas-relief with sculpture in the round; Early Dynastic III period



Votive alabaster vase from Warka with ritual scenes; Protoliterate period

Fragment of square plaque from Khafajah, to which a fragment of a similar plaque from Ur has been added (lower left corner); Early Dynastic II period

Spouted vase with stone inlays; Protoliterate period

Sculptured steatite cup in a low cylindrical shape with a flat bottom; Early Dynastic II period. From Khafajah

Vase from Warka with spout flanked by two lions sculptured in the round; Protoliterate period

Basalt stele depicting a lion hunt, with figures in dress characteristic of the Protoliterate period. From Warka

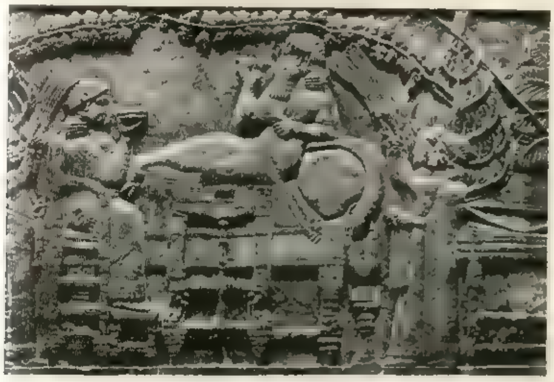
Two fragments from obverse side of "Stele of the Vultures" of E-anna-tum, ruler of Lagash; Early Dynastic III period

BABYLONIAN AND ASSYRIAN RELIEF SCULPTURE

Victory stele of King Naramsin, commemorating his triumph over the Lullubi; Akkadian period. 23rd century B.C. From Susa

Bas-relief on top of the stele inscribed with Hammurabi's code, showing the king before sun god Shamash; Old Babylonian period. 18th century B.C. From Susa

Monumental stone relief of a winged human-headed bull (*lamassu*) from the palace of Sargon II, king of Assyria, (722–705 B.C.). From Khorsabad



Assyrian relief from the palace of Ashurbanipal, king of Assyria (669–630 B.C.), showing the king and queen dining in the garden. From Nineveh

Altar of Tukulti-Ninurta I (1245–1208 B.C.) showing the king approaching and kneeling before altar bearing emblem of the fire god Nasku. From Ashur

Assyrian relief from the palace of Ashurnasirpal II, king of Assyria (884–859 B.C.), showing the king hunting lions. From Nimrud

BABYLONIAN AND ASSYRIAN RELIEF SCULPTURE

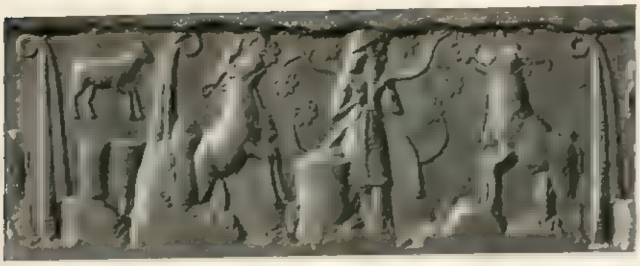
BABYLONIA AND ASSYRIA



Feeding the sacred herd, impression from a seal from Warka: Protoliterate period

Horned animals engraved in the "brocade style" from a seal found at Tell Asmar; Early Dynastic I period

Contest scene of human and superhuman beings in conflict with animals and monsters; Early Dynastic II period

Struggle between human-headed animal[illegible] beasts, including lions, from seal of the Early Dynastic III period

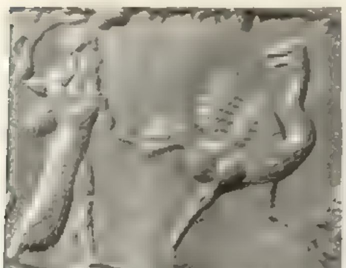
Combat scene showing bearded hero and bull-man struggling with beasts; Akkadian period

Presentation scene showing two go[illegible] horned hats leading a worshiper to meet a seated god; Ur III per[illegible]

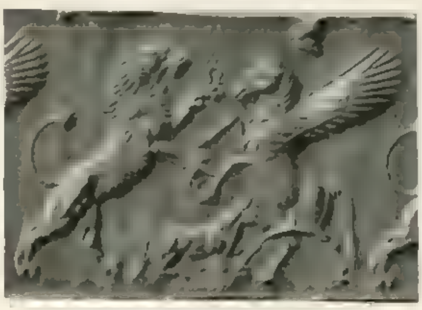
Presentation scene with worshiper bringing an offering; Old Babylonian

Seal impression from the Kassite period with seated deity and inscribed prayer

Cylinder seal impression of the Mitannian style



Hunting scene with winged hero pursuing an ostrich; Middle Assyrian period



Middle Assyrian cylinder seal impression showing a lion and winged horse in combat

Cylinder seal impression of the New Assyrian period with a winged genius gripping two winged bulls

BABYLONIAN AND ASSYRIAN CYLINDER SEAL IMPRESSIONS

valleys, defeated the Assyrians near Harran and received tribute from the north Mesopotamian tribes. In this situation Sin-shar-ishkun concluded an alliance with Psamtik of Egypt. In 615 Nabopolassar besieged Ashur but had to retreat upon the approach of an Assyrian army; in the autumn of the same year the Medes marched against Arrapkha (Kirkuk). In 614 the Medes advanced from there via Kalakh to Nineveh, but for unknown reasons they did not begin a siege of the capital but rather took the town of Tarbisu, northwest of it; from there they turned south against Ashur, which they besieged and conquered. Nabopolassar came to their help but arrived at Ashur only after the city was taken; he then concluded a formal treaty of alliance with Cyaxares, after which both kings returned home.

During 613 Nabopolassar operated on the middle Euphrates, where he met the resistance of an Assyrian army. In the following year, 612, both the Chaldeans and Medes besieged Nineveh, which they took in the month of Ab (August) of that year. The city was looted and completely destroyed, never to be rebuilt again. The chronicle has a broken sentence about Sin-shar-ishkun in this connection; if one is to believe the later tradition about "Sardanapalus" one may restore it to mean that the king died in the flames of his palace. Following the conquest of Nineveh, Cyaxares went home, while Nabopolassar continued his military operations in the direction of Nisibin (Nusaybin), west of Nineveh. Still farther west, an Assyrian named Ashur-uballit II set up a last Assyrian kingdom in Harran. Against him Nabopolassar operated during the next years. In 611 he reached Til Barsib on the Euphrates but did not attack Harran itself yet. But in 610 Nabopolassar was able to take Harran, although an Egyptian army had now appeared on the scene. Ashur-uballit abandoned Harran. In 609 he and Necho II of Egypt tried to recapture it but had to give up that plan upon the approach of Nabopolassar. While Ashur-uballit is no longer heard of after this unsuccessful attempt, Nabopolassar continued his campaign northward into Urartu, where he returned also in 608. Thus, after the fall of Nineveh in 612, the fall of Harran in 610 and Ashur-uballit's attempt at reconquering the latter in 609, Assyria ceased to exist.

3. Neo-Babylonian Kingdom.—The Chaldean dynasty that came to rule over Babylonia with Nabopolassar (626–605) remained in power for a little less than one century and brought about a last period of flourishing. The Assyrian empire was divided between the Medes and the Chaldeans: northern Assyria and Anatolia were taken by the Medes, whereas the south became Babylonian. In Syria the Egyptian army that had helped Ashur-uballit remained, and Nabopolassar turned against it. Fighting went on during 607 and 606, mainly in the region near the bend of the Euphrates; in these campaigns Nabopolassar's son, the crown prince Nabu-kudurri-usur, took part with his father. With the year 605 a new tablet of the chronicle begins. In that year Nabopolassar stayed at home and sent his son against the Egyptians. They were defeated by the crown prince in the battle of Carchemish (*q.v.*). The remnants of the Egyptian army were pursued and annihilated near Hamath on the Orontes, and subsequently Nabu-kudurri-usur conquered "all of Hatti"; *i.e.*, Syria. On the 8th of Ab Nabopolassar died, and his son hurried home to succeed him on the 1st of Elul.

Nabu-kudurri-usur II (605–562; the biblical Nebuchadnezzar or, according to a better reading, Nebuchadrezzar) ruled for 44 years and marks the peak of the Chaldean or Neo-Babylonian kingdom. During the first years of his reign he continued the pacification of Syria, where the chronicle reports his activities for all the years from 604 to 595 (the end of the extant text). For 601 it lists an indecisive battle against an Egyptian army in Palestine. The siege and first conquest of Jerusalem in 597 is also mentioned in this chronicle; the story is known from the Bible. King Jehoiachin was taken to Babylon as prisoner; accounts listing the rations he received there during his captivity were found in Nebuchadrezzar's palace. In Jerusalem, Nebuchadrezzar installed a new king, Zedekiah, who paid him tribute. About Nebuchadrezzar's later years we are not so well informed. For 595 the chronicle mentions the suppression of a revolt in Babylonia. The second and final conquest of Jerusalem in 587, following a revolt of Zedekiah, who had the help of Apries (Hophra) of Egypt, is known from the Bible, while the letters found at Lachish illustrate one episode of this last struggle of Judah. The Babylonian captivity (*q.v.*) was the result of this historic event. (*See* also NEBUCHADREZZAR.)

In Babylonia the reign of Nebuchadrezzar was a period of prosperity and restoration. Almost all the palaces and temples excavated in Babylon date from his reign. The rebuilding of the famous ziggurat of Babylon, which became known as the tower of Babel, was begun by Nabopolassar and completed by Nebuchadrezzar. Found in excavation was the processional street that led from the Ishtar gate to the main temple of Marduk, Esangila; both the gate and the walls of the street were decorated with reliefs of lions, bulls and dragons in colourful glazed bricks. (*See* also BABYLON.) Similar glazed bricks also adorned the front of the throne room facing the courtyard in one of Nebuchadrezzar's palaces. In one palace, a very strong vaulted substructure was found which is believed to have carried what the Greeks later called the hanging garden of Semiramis.

Literature flourished and texts were copied in the schools. Marduk, in this period mostly called Bel, "the lord," superseded most other gods, so that in this period Babylonian religion moved toward some kind of henotheism. Simultaneously the different gods or manifestations of Bel were equated with astral bodies, and astrology was further developed. This Neo-Babylonian civilization is the one that became known to the Greeks and Jews. Writing, even of private documents, went on in Akkadian, although Aramaean was the language spoken by the majority of the people.

The successors of Nebuchadrezzar were short lived and insignificant. Of Amel-Marduk (Evil-Merodach; 562–560) hardly more is known than the fact, attested by the Bible, that he pardoned Jehoiachin. His brother-in-law and successor Nergal-shar-usur (559–556; Neriglissar according to Berossus) tells of building activities in his own inscriptions; a chronicle text mentions a campaign of his in Cilicia. The lawful heir, Labashi-Marduk, a minor, was assassinated in 556, and in his stead a usurper, Nabu-na'id, seized the throne.

Nabonidus (Nabu-na'id; 556–539), the last Babylonian king, is one of the most enigmatic figures. His mother was from Harran, and he himself had strong ties with that city and particularly with its moon-god. A derogatory poem, written after his end, blames him for having made the moon-god, Sin of Harran, the supreme god of Babylon instead of Bel-Marduk, and the chronicle also states that under him the New Year festival, the great festival of Marduk, was not celebrated for several years. For 12 years Nabonidus stayed in Arabia, where he conquered the oasis of Tema (Taimah) and then used it as a base for further conquests in the Arabian peninsula. During his absence, he installed his son Bel-shar-ushur as viceroy in Babylon; the Bible (Dan. v) knows him as "King" Belshazzar (*q.v.*). (*See* NABONIDUS.)

The most dangerous enemies of the Neo-Babylonian kingdom were the Persians. A Persian ruler, Cyrus II the Great, had shaken off the overlordship of the Medes by defeating their king, Astyages, in Nabonidus' first year (555). Harran, which the Medes had held since 610, was taken by Nabonidus as a consequence of their defeat, and he immediately began the rebuilding of its moon temple. But Cyrus went on to enlarge his realm. After having taken Ecbatana (Hamadan), the old capital of the Medes (550), Assyria and all of Anatolia, where he defeated Croesus of Lydia and conquered Sardis (547), he brought the rest of Iran under his rule, thus replacing the kingdom of the Medes by his own Persian empire.

To take Babylonia and with it Syria was the logical next step. Nabonidus finally returned home to defend his country. Historians still puzzle whether his sojourn in Arabia was a sign of unawareness of the Persian danger, or whether he tried to secure the resources of the Arabs against this danger. At any rate it was too late. After a short war Babylon was taken without fighting in 539. There Cyrus acted as the restorer of the old order, and the above-mentioned poem duly praises him as the legitimate king who returned Marduk to his old rule. Syria automatically fell to Cyrus once Babylonia was his, and the two regions became one

satrapy of the Persian empire. This is the end of the history of Babylonia.

4. Persian and Seleucid Eras.—Under the Persian kings Babylonia remained a province of their empire and seems on the whole to have been prosperous. The Achaemenid kings used the Akkadian language for their royal inscriptions alongside Old Persian and Elamite (these trilingual inscriptions were the first to be deciphered in modern times; *see* CUNEIFORM). Legal and business documents continued to be written in Akkadian; they were dated after the regnal years of the Persian kings. Some Babylonian firms transacted business with the "great kings"; in the administrative documents Persian terms appear as loan words. Revolts occurred at the accession of Darius and later and were suppressed. When Alexander the Great conquered Babylon in 330 B.C. he found the ziggurat or temple tower, which Herodotus had seen still standing about 100 years earlier, completely destroyed. This destruction has been explained as due to Zoroastrian fanaticism under the later Achaemenids. Alexander ordered the site to be cleared, but the work of reconstruction was never completed. A theatre and other Hellenistic buildings were found in Babylon by the excavators. Gradually, however, the founding of new cities for the Macedonian soldiers, and especially the foundation of Seleucia on the Tigris, led to the desertion of Babylon while other cities continued to exist. Especially the scribal school at Erech remained active all through the Seleucid period, collecting ritual texts and developing astrology. From the Seleucid period comes the compilation in Greek of a work on Babylonian history, ascribed to a certain Berossus, parts of which are preserved through quotations in the books of later Greek writers. (H. G. GK.)

IV. CIVILIZATION

A. ECOLOGY, ETHNOLOGY AND TECHNOLOGY

1. Ecology.—The lower valleys of the Zagros region, the piedmont and the banks of the rivers of Mesopotamia proper lend themselves readily to agriculture and offer ample pasture. The main cereal crop of the region was barley, dependent on rainfall in the northwestern part of the country and on irrigation in the southeast, while wheat was grown to a smaller extent, and millet still less. Equally important with barley were sesame, with its oily seeds; several leguminous plants; and fibre-yielding flax. A considerable variety of domesticated savorys (garlic, onion, leek, etc.) and other spice plants were known. In gardens, dates, which provided an essential part of the diet, were cultivated according to techniques learned very early, while such fruits as figs, apples, pears and pomegranates were of less importance. Wine likewise was produced, though beer made of barley was a much more popular alcoholic beverage. Herds of goats and several breeds of sheep provided a supply of meat and milk (used for butter and cheese); the hides, hair and especially wool were of great economic importance. Cattle, needing seasonal transhumance, were kept mainly by the palace and the temple. River, lake and sea fish were used widely as food only up to the middle of the 2nd millennium B.C. and that with constantly decreasing frequency; after that time, fish seems hardly to have formed a part of Mesopotamian diet. Fowlers caught and tended ducks, geese and a number of other birds difficult to identify. The chief object of hunting was to decrease the number of wild animals preying on the flocks rather than to obtain food.

The region lacked timber suitable for building, and stone was available only in the northwest, apart from an outcrop in the far south. The commonest building materials were clay (used in pisée technique, but mainly in brick form) and, in the southwest, reeds, which grew to a great height in the extensive canebrakes. Metals could be obtained only through trade or war.

Under such conditions, communities of barley farmers sprang up in villages situated at first in the fertile valleys, and later spreading into the alluvial land, where at first small-scale agricultural engineering (dikes, drainage and distribution canals) was practised and then, gradually, constructions developed to serve larger sections. Farmers got their water from the crest of the annually flooding rivers; mechanical lifting devices were relied on only for gardens. The settlements seem to have been small, unfortified villages, which, in Babylonia proper, tended to cluster along navigable waterways. During the entire history of the irrigated region, flood catastrophes and gradual salination of the over-used soil forced constant shifting of settlements. When the phenomenon of urbanization took place in the southwest, these same factors contributed toward repeated dislocation of political power from city to city. In contrast to the agglomerations of cities along the several courses of the Euphrates and possibly along the large canals fed by that river, urban settlements were rare in the northwest, where only the stimulus of political, administrative or military needs could cause them to start and to flourish.

The northwest was the habitat of small farmers living in villages, of nomadic shepherds who moved slowly but continuously with their flocks, a region that had to be forced by a central authority into accepting urbanization and what it exacted in taxes and services. There any weakening of the executive power of the central authority led immediately to a collapse of communications and of the services needed to support the political integration of the region and thus to the return to the type of fragmentation that constituted the natural political organization of northwest Mesopotamia and a number of adjacent regions to the west.

Characteristic features of Mesopotamian cities were the large and often doubled crenelated brick walls sweeping around the settlement in straight or curving lines, studded with cavalier towers and interrupted by monumental gates. In the south the temples were placed by themselves within an *enceinte* inside the city walls, while in the north a citadellike interior fortification guarded palace, temple, treasury and the barracks of the soldiery as an "inner city" that, quite often, was located astride the main wall. The multiple-staged temple tower (ziggurat), often decorated with coloured glazed bricks, was a characteristic of the silhouette of the Mesopotamian city. Outside the walls was a fringe of gardens, fields and scattered houses that, as a rule, grew into suburbs (for which the Sumerian and the Akkadian languages have special designations). The harbour was likewise beyond the walls; its function was to link the originally quite autarchic city to the economic life of the outside world, and it enjoyed for this very purpose a special legal and administrative status.

2. Ethnic Composition.—A series of invasions and intrusions, either from the semidesert regions to the west or from across the mountain barriers to the north and the northeast, characterize the entire history of Mesopotamia. They are reflected in the culture sequences of the preliterate period as well as in the historic records of the subsequent three and more millenniums. At an undatable point in the late preliterate period there seems to have occurred a fusion of several distinct ethnic and cultural assemblages that produced a *sui generis* Mesopotamian civilization. To this civilization Sumerians and early Semites contributed essentially, and a complex substratum must be assumed, but the extent of the contributions of this to the general culture is a moot question. This composite Mesopotamian civilization is known, first, up to the beginning of the 2nd millennium, through Sumerian texts, and then, after a transition period, through texts written in the dialects of the Semitic Akkadian language. As to material remains—such as works of art, pottery, tools and traces of buildings—the evidence dating up to the end of the 3rd millennium is richer, more varied and more impressive than that of the subsequent periods with the exception of certain remnants of the Neo-Babylonian age. This seems to be due to the frequent shifting of the seat of political power, which often spared the artifacts and buildings of the earlier settlements of the south the wear, tear and loss concomitant with continuous habitation; in contrast, in the north, where this power remained stationary often for very long periods, settlements are less well preserved.

The Mesopotamian civilization that arose in the densely urbanized stretches along the lower Euphrates, to conquer and to influence vast regions of the near east, remained itself characteristically open to foreign impulses and seems to have been able repeatedly to learn and to derive increased vigour from contacts with conquerors. Understanding of the culture development in the northwest, in Assyria, is still far from clear, but it

seems that a more or less coherent body of foreign mores (usually referred to as Hurrian; *see* HURRIANS) was instrumental in endowing certain essentially Assyrian culture traits (such as the status of the city of Ashur, the position of the Assyrian king, etc.) with enough strength to create there an important variant of Mesopotamian civilization. The decline in vigour of this civilization can be observed as early as the beginning of the 1st millennium B.C. This decline is evidenced chiefly by the introduction of a new system of writing, whose slow but irresistible spread severely restricted the expansion of the Akkadian literary tradition and divorced it gradually from contact with the spiritual life of the community. The ever-increasing linguistic barrier between the Aramaic-speaking population and the Sumero-Akkadian scribal tradition, rather than the loss of political independence through the Persian and eventually the Greek conquest, brought the long-lived Mesopotamian civilization to an end.

3. Technology.—Technologically, Mesopotamia in the 4th and 3rd millenniums was part of that chain of civilization foci that stretched from India to northern Africa between the zones of mountain forest and tropical forest, savannah and desert. It shared with them a stock of domesticated food plants and animals to which it seemed to have contributed of its own such essential cereals as barley and possibly wheat, as well as the wool-bearing sheep. Moreover, Mesopotamia repeatedly transmitted such plants and animals from the eastern to the western members of that chain. A common fund of techniques connected with these animals and plants was in evidence even in the formative stages of all these civilizations. These techniques pertain to farming and horticulture, to simple metallurgy and weaving, to rather advanced potterymaking and working of stone for ornaments and tools, to tanning and to the use of clay (in brick form) and wood for building.

In Mesopotamia proper may be observed an energetic development in some of these techniques—as architecture on a monumental scale and the sophisticated use of metals and stone for works of art—as well as an increase in the quantity of production of foodstuffs and raw materials under the pressure of urbanization. This early bloom was soon replaced, however, by technological stagnation and even impoverishment. The arrest in the development of Mesopotamian technology was to some degree counteracted by its readiness to accept foreign techniques and even sometimes to improve upon them. The glazed-brick wall decorations in relief, the few extant products of the late (New Assyrian and Neo-Babylonian) metallurgy (if not the work of imported craftsmen) and the architecture of the later periods (which surpasses earlier achievements not merely in size) are instances of such development. The arts of the seal cutters and jewelers, however, could not reach the levels of earlier achievement; and pottery, agriculture and animal husbandry show progressive stagnation. In such arts as metallurgy, shipbuilding and weaving the later periods openly acknowledged foreign supremacy.

Nevertheless, seen from the point of view of the world history of technology, the Assyrian conquests and the subsequent short flowering of the Chaldean empire contributed essentially toward an intensification of technological contacts within the ancient near east, including the adjacent regions to the north, the west and the east, and these contacts came to exercise long-lasting influences and stimulated diffusion of technical knowledge far beyond the frontiers of Mesopotamia. (*See* also above, *Archaeology, Architecture and Art.*)

B. Social Structure

Any reconstruction of the nature and temper of Mesopotamian social structure depends necessarily on the nature and content of the available evidence, particularly the written evidence. A complex and only vaguely known internal development and a wide range of important regional differences make it difficult to present this topic in other than general terms.

A primary characteristic of Mesopotamian social structure is the absence of any status stratification, if the unique status of the king and the always small slave population are excluded from consideration. No warrior class arose as a result of the conquests, nor did the special status of the priests create any tensions between them and the rest of society. The social structure was dominated (1) by the contrast between city dwellers and those who lived outside the walls, and (2) by the contrast between those elements of the population that were incorporated in the socio-economic organizations of temple and palace as against those who lived on small-scale agriculture, on the skill of their hands, etc., in cities, villages and encampments of all kinds. These two contrasts are the more important as the family played only a rather limited role in the social structure.

1. Family.—The family was small and restricted, though there are indications that it was more extended and complex in the Sumerian period and in certain marginal regions of Mesopotamia. In both instances are found traces of what may be termed tribal or clanlike organizations, which seem to recur again in the late period as an expression of foreign mores. The family could be enlarged by the adoption of small children or manumitted slaves who were to provide care for childless old persons, but these practices disappear or become extremely rare after the middle of the 2nd millennium B.C. Later periods show a measure of family consciousness by the use of ancestral as "family names" (for identification purposes), and also by a certain emphasis on gentility in general and on descent for certain professions. The head of the household had one wife; only in the Old Babylonian period are references made to a second wife, of lesser rank, though the social status of women was at that time higher than in the later period. The first-born son received a preference share in the paternal estate, and provisions were made to ensure the daughters' dowries and the younger brothers' marriage expenses. Normally, brothers held the inherited fields in common to avoid their division into small lots; they often lived with their families in the father's house. In the peripheral regions, as Elam and northern Assyria, some foreign influence on the family structure is clearly in evidence, just as certain vestiges of earlier customs maintain themselves (*e.g.*, the position of the mother's brother) in the early Babylonian tradition.

2. Slavery.—Outside the family stood slaves, persons with restricted freedom and isolated individuals. Documents dealing with the division of property show that there were never more than a few slaves in private possession. Those born in the house seem to have enjoyed a special status, as compared with those acquired from outside, at least in the Old Babylonian period. Later, slaves were allowed to work for their own living under the obligation of making monthly silver payments to their masters. The latter often had them articled out to learn profitable crafts in order to increase their earnings and, consequently, the master's share. Originally slaves were either debtors or their children, also foreigners who were imported for their special skills and services. Only rarely were they prisoners of war. The institutional slaves owned by the palace or temple had a somewhat different status but seem to have been recruited similarly, though many more prisoners of war must have been among them. They were utilized for all types of work and apparently could reach important positions.

Persons of restricted freedom (*i.e.*, neither free nor slaves) were attached exclusively to temples and palaces. They received food rations (according to age and sex) for work in fields and shops, but their exact social and legal status remains uncertain. They were numerous in the early periods, but little is known of their ethnic or social provenience. In the later periods (Erech of the Neo-Babylonian and Persian kings) they belonged mainly to the temple and seem to have enjoyed the same liberties as the privately owned slaves of that time.

Isolated individuals are rare, since slaves were normally manumitted into the family and foreigners had to have royal protection (as envoys or refugees) or to live in special quarters as merchants or craftsmen. Still, the name of a number of persons in the Old Babylonian period is Refugee; they may have been runaway debtors or displaced persons.

3. Associations.—Since family ties were ineffective throughout the region and clan relationships were not in evidence in cities and villages, other forms of associations assumed the function of

providing status and security for their members. These associations were professional, religious or political, using the last term loosely and generally.

Professional.—Guildlike associations of craftsmen and merchants under foremen disappeared after the Old Babylonian period, though a number of later family names may indicate some survival of such institutions. Certain craftsmen, such as tanners, fullers and smiths, however, continued to live together in special quarters of the city, to which they seem to have been restricted. In the Nippur of the late Persian period are found, perhaps as a survival, indications that suggest the existence of guildlike structures. Special circumstances contributed to the formation of associations among certain trained experts in exorcism and divination techniques. These professionals were sophisticatedly organized; candidates for membership had to be acquainted with a number of reference texts, pass what seem to have been competitive examinations and meet certain physical and status requirements. Scribes likewise seem to have undergone extensive formal training in order to preserve the traditions of their craft and apparently were organized in families (natural or artificial).

Religious.—Religious associations were rare, existing only in the Old Babylonian period. The concerns that normally give rise to such associations—for the souls of the dead and for the maintenance of specific cults—are conspicuously absent from Mesopotamian culture.

Political.—Political associations were of two types, understanding of which is essential for gauging the characteristic temper of the social structure. One type was centred in the city, the other in the palace and the temple. Thus, the former is ecologically conditioned, the latter economically, with slightly differing ideological superstructures.

Within the confines of the city walls the consciousness of belonging was shared by the community of persons of equal status, mainly farmers who lived off fields and gardens that extended in a green belt around the city. They ran their affairs through an assembly in which, under a presiding officer, some kind of consensus was reached on communal matters. Very little is known about the functioning of this type of government, but the absence of all those complex and elaborate practices that in the Greek *polis* served to control the ambitions of individuals to exercise power over their fellow citizens may be noted. The deeply agonistic mood of the Greek city is in strong contrast to the situation in the Mesopotamian city, which resembles, if anything, a tribal group in which the superiority of the richer, the older or otherwise influential members is willingly accepted.

The city harboured as the divine guarantee of its continuity and identity the house of the deity, in which was centred its religious life as a community. From the earliest period, some kind of coexistence seems to have been reached in the Mesopotamian city between, on the one hand, the self-governed community and, on the other, the temple with its personnel living in its own economic world, as well as the palace of the king, whose sway extended beyond the city walls. Throughout its entire history, the Mesopotamian city had to come to terms with these two essential institutions: temple and palace. A flourishing temple and a palace full of the spoils of war or tribute cannot have failed to affect the city economically and politically. Such conditions must have produced widely differing relationships in individual cities and in specific periods. Often the economic basis of the city was affected by the impoverishment of the arable soil, while, on other occasions, the citizens succeeded in shifting their capital investments from agricultural holdings to manufacture and export trade, which could create accumulations of capital that influenced the city's relation to the royal power. At a time when the economic importance of the temple gradually declined and the palace's influence correspondingly rose, royal officials, with functions that cannot be determined, were put into the city. Beginning with the end of the 2nd millennium, more and more is heard about the struggle of the old cities Nippur, Sippar and Babylon in Babylonia and Ashur and Harran in Assyria for the preservation of specific exemptions and privileges upon which the royal authority tended to infringe. These were mainly exemptions from military service and forced labour, freedom from taxation of all kinds, protection against military intervention within the city limits and security for overland caravans. It seems that the Assyrian kings had to grant to individual cities charters that specified these privileges, yet it is clear that political conditions rather than a well-established tradition determined their extent. The loss in revenues that occurred whenever these exemptions were respected seems to have been severely felt, and the constant endeavours of the Assyrian kings to build new cities in order to force displaced and unsettled segments of the population into urban living and hence into payment of taxes and rendering of services clearly were meant to remedy this situation.

Entirely different in structure and temper from the community of citizens were the two organizations that coexisted within the city: temple and palace. Both shared the characteristics of closed economic systems, in which goods and services are channeled into and circulated through a strict hierarchic structure. Income from agricultural holdings, taxation, trade or war was directed to a central administration that in a well-regulated pattern disposed of it to support, by means of rations and special shares, the administrators and workmen that served and directed the system. These systems differed little as between palace and temple. Both were basically households, the palace that of the king and the temple that of the deity, the latter conceived of as residing in its cella, to be fed, clothed and cared for as was the king on his dais. The status of the members of these households differed essentially from that of the city community; they were either slaves of the god or the king, or persons of restricted freedom, or attached in some other way to the lord of the manor. Their number varied according to the importance of the household and was easily increased by prisoners and by free persons who attached themselves to the household, either because of famine or because their talents (as those of certain craftsmen and artists) could best serve them within the organization of temple and palace.

Notwithstanding the many common features, important differences separated the temple, on the one hand, and the palace, on the other, and there was, furthermore, a wide range of variation among the palaces and among the temples. The military and political power and ambition of the ruler determined the size and composition of the palace organization needed to administer the realm, to organize warfare and to build and to rebuild cities and temples. Important local differences, mainly those between Babylonia and Assyria, and differences due to outside influences and specific historical developments also made themselves felt. Such qualifications likewise apply to the sanctuaries, where the requirements of certain cult practices cannot have failed to influence the internal organization of the temple, and where the degree of royal largess, rather than the returns on agricultural investment and the pious generosity of worshipers, eventually came to determine the wealth and splendour of the god's household.

This latter development is part of the complex history of the relations between the palace and the temple during the three millenniums of Mesopotamian documentation. It is characterized by the continuous rise in importance of the palace, from the manor of the Sumerian *lugal* to the splendour of the extensive structures of the New Assyrian and Neo-Babylonian kings (in Nineveh and Babylon), and the corresponding decrease in economic strength and importance of the temple, down from the vast organizations of the Sumerian period with their armies of slaves and serfs. The riches and world-wide fame of the late temples must not make us forget that the influence of the sanctuaries was socially and economically on the decline from the time of Hammurabi.

The redistributive organizations of temple and palace, emphasizing personal achievement and talent in spite of the necessarily hierarchic organization, allowed the individual more mobility than the city did. Individuals could and did move into temple and palace from the static and quasi-tribal realm of the city, where status and wealth stabilized the social structure and where it apparently was impossible for a person not born a citizen to become one, except, perhaps, by adoption.

Theologically, the temple's function was to ensure adequate materialization of the divine presence within a human-shaped image that lived in its cella and was maintained by offerings and served by the staff of the sanctuary. This organization aimed at economic independence secured by agricultural holdings and manpower. The output of the temple's textile workshops was used to obtain by barter from the mountain regions the stone, metal and timber needed to adorn the house of the god. From victorious kings, the temple expected the dedication of prisoners of war, of a part of the booty, and votive offerings. In the course of time, the kings were made to see in the restoration and embellishment of existing sanctuaries and in the building of new and larger temples and temple towers a royal privilege and duty toward the gods. In the late periods, though, royal commissaries are found on the administrative boards of the most famous temples to ensure the payment of taxes due to the king.

The cultic relation of the king to the city's deity found expression in certain functions of the ruler within the annual cycle of festivals that served to display the essential importance of the deity for the entire community. With the rise of the royal power and the wider scope of its political ambitions, the king's cultic functions ceased to be carried out in actuality and were maintained only in the references to them in the solemn royal titularies. The situation in Assyria that may be seen in documents of the turn of the 2nd millennium and later was different, inasmuch as the Assyrian king was the high priest and representative of the national god Ashur; this endows the Assyrian kingship with theocratic connotations that are conspicuously absent in the Babylonia of the 2nd and 1st millenniums.

It should be stressed that the influence of religion on the individual, as well as on the mood and temper of the society as a functioning whole, was at all times small in Mesopotamia. Ritual and ideological requirements made few demands on the individual's physiological appetites or psychological preferences. They laid no claims on his body or on his time and caused no conflicts of loyalties. Death was accepted in a matter-of-fact way, and the individual's participation in the temple's cult was extremely restricted, mainly to participation as an onlooker in certain public ceremonies. Private piety is little in evidence.

The temple was run by a priestly college (well attested for the later periods) under a chief priest. The priests derived their income from the temple's animals and staples "offered" to the image in prescribed forms and quantities and thereafter distributed among them according to a fixed rate. These priestly incomes were inherited, given as dowries and generally negotiable. This practice contributed effectively to keeping the divine repasts and essential aspect of the cult in the sanctuary.

The position of the king in Mesopotamia was in war that of the leader of the army, while his responsibilities in peacetime were social rather than cultic, although the latter aspect is, as stated above, in evidence as a special development in Assyria. The king was the guarantor for proper legal procedures and the protection of the underprivileged; he discharged these duties by hearing appeals, by regulating the rates of interest and maintaining the standards of measures, and by regulating the prices of staples and the wages and fees for essential services. Traditionally, the king promulgated laws and price regulations, both meant to correct abuses and to adjust practices to the needs of those whom they affected, and showed new ways to judge responsibilities in conflicts of interests. Still, the Code of Hammurabi and a number of similar extant Sumerian and Akkadian codifications do not show any direct relationship to actual legal practices; they rather present themselves as a traditional literary expression of the king's social responsibility and his awareness of the gap that separated existing conditions from those that were considered desirable. As such, these codes represent an interesting formulation of social criticism, but they should not be considered normative directions in the nature of the postbiblical and the Roman law.

C. Economic Conditions

Economically, Mesopotamia suffered under the blight that besets cereal farmers everywhere: the burden of debt that ruins the farmer relying on barley as a main crop, the tax claims of the administration and the practice of farming out the actual work on the land. In addition, Mesopotamia had to contend with soil deterioration and the economic disequilibrium caused by the large domains of the temples and palaces. The kings of the dynasties up to the end of the Old Babylonian period combated the continuous crisis with repeated releases of all noncommercial debts, with redistribution of ameliorated land, with regulations concerning rates of interest, etc., all apparently without much success.

Accumulation of wealth in precious metals, cattle or real estate normally was restricted to the two institutions of palace and temple. Only exceptionally is evidence found that private initiative was successful in that respect. Such an instance is offered by the Old Assyrian merchants in their overland trade dealings (for which nearly all evidence comes from Asia Minor) at the beginning of the 2nd millennium, and, most likely, by the merchants of Ur, a little later, who seem to have imported copper from overseas. Then, in texts of the Old Babylonian period there are certain indications of accumulation of wealth in the hands of merchants (in Eshnunna, Larsa and Sippar) who also worked for the palace and under the protection of the latter. For a merchant to operate under the protection of the palace became the rule from the middle of the 2nd millennium onward all over the ancient near east. With the end of this millennium, evidence for overland trade becomes rare and indirect.

In the Old Babylonian period, silver was used as a standard rather than as a means of payment, staples being handled for that purpose, while in the later periods of Babylonia and Assyria, silver actually was weighed out, coins (only in small denominations) being used solely in the last century of the Assyrian empire.

Although in Mesopotamia nearly all power and wealth were always in the hands of those connected with temple and palace, there are hardly any allusions in literary, historical or other texts to discontent with or rebellion against this situation, which must be taken to indicate a satisfactory functioning of the socioeconomic structure. The well-known passages from the Bible and contemporary Egyptian sources expressing social criticism put the Mesopotamian acceptance of the *status quo* in relief. The sizable body of Sumerian and Akkadian texts that attest to far-reaching social changes and economic reorientation all seem to suggest that they were introduced by royal initiative.

D. Intellectual Achievements

An essential if not the main achievement of Mesopotamian civilization was the early development of an effective system of writing that was put to several uses. The administrations of temples and palaces left records of large transactions and dispositions and, to a lesser extent, communications. Religious, historical and literary texts appeared early and blossomed quickly into a variety impressive in form and content. After several centuries of intense flowering, a process of fossilization set in that affected a large section of Mesopotamian literary production. It seems to have been furthered by the scribal practice of preserving by constant copying and recopying an extensive body of texts containing the numerous essential handbooks and reference works of the diviners and other professionals, including the textbooks (dictionaries, grammars, etc.) necessary for the correct training of the scribes, and, eventually, such purely literary tablets as epics and wisdom texts. This practice contributed toward maintaining a tradition that securely welded content and style to the system of writing and even the writing material, protecting the tradition against the effects of time and changing realities. However, it created a fateful gap between the static body of traditional texts and those writings that were the products of individual creativity and of specific cultural situations. These were set down only in a few or even single copies and have to a great extent disappeared, robbing us of the possibility of directly observing intellectual development in Mesopotamia. This situation and the effects of the changes in language (Aramaic for Akkadian), the system of writing and, especially, the writing technique (ink on leather and parchment) caused a progressive shrinkage of the literary tradition. (*See* below, *Literature.*)

If the achievements of Mesopotamia are judged in their effect on neighbouring and later civilizations, astrology and mathematical astronomy would have to be mentioned in the first place. Both spread toward the west as well as toward the east. Astronomy represents a very late development in Mesopotamian intellectual history that came to fruition in spite of a vigorous and persistent interest in astrology. Mention also should be made of the diffusion of administrative techniques and court ceremonial from Mesopotamia via the Sassanid court to Byzantium (and eventually to medieval Europe), and the far-reaching influences exercised directly, or by stimulus or osmosis of technological practices, iconographic motifs, the characteristic metrology, etc. (A. L. O.)

V. RELIGION

A. Growth and Development of Religious Thought

1. Wills to Natural Phenomena.—The basic characteristic of ancient Mesopotamian religion was a tendency to a pluralistic view of the numinous (*i.e.*, the mysterious element in the holy and the feelings of awe or fear it elicits): many different numina (or divine powers) were seen in many different phenomena, each such numen being the life force and will of its particular phenomenon, namable from the phenomenon and wearing the external form of the phenomenon. As an example of the last, representations from the Protoliterate period show that the numinous power in the rain cloud, Imdugud, was given form as an enormous lion-headed black bird, floating on outstretched wings and roaring its thunder cry.

With the numina that constituted the will of phenomena vital to human survival, especially those phenomena that were essential to the economy—as flocks and herds, grain, the earth, etc.—man felt a sense of solidarity that found its expression in endeavours to ensure the "presence" of the numen by such means as cult images, temples, service and the ritual drama. The earliest Mesopotamian religion appears to have been one of solidarity with nature and its powers, upon which man depended.

This early tendency to give situationally determined, nonhuman form to the numinous, however, probably at no time excluded attribution also of human form. Thus the Erech vase, which dates to Protoliterate time, shows the sacred marriage between two deities in human form, and so do numerous representations on seals from this period. The fact that human agents could embody the gods and take on their identity in the ritual drama also indicates that the human form as such must have been considered possible and appropriate for divinity.

Nonetheless, attribution of human form to the divine did not come to dominate religious thought until Early Dynastic times. From the latter half of that period onward it is the form under which gods and goddesses ordinarily are represented. The older nonhuman forms, with their close ties to natural phenomena, tended to recede into the background as divine emblems (*shu-nir*) associated with the anthropomorphic god—the sun disk next to the human figure of the sun-god Utu, the lion-headed bird accompanying Ningirsu/Ninurta, the ibex accompanying Enki and the dog associated with Nininsina. At times animosity against the now unpopular older form even seems to have made of it an enemy vanquished by the human-shaped god; in later mythology, for example, the lion-headed bird develops into the chief opponent of the god Ningirsu/Ninurta whose older form it is. Parallel to this process of divorcement of the older nonhuman form from the human form of the god there seems to go a similar general tendency to divorce phenomenon from god and to see it as a distinct, not divine entity. The god comes to own or control the phenomenon, becomes a power behind it rather than in it and of it.

2. Anthropomorphic Ruler Gods.—The victory of the human form was not easy or rapid and for long periods not complete. Enanna-tum I at the end of the Early Dynastic period still was depicted in attitude of worship before Ningirsu's old form of lion-headed bird. As late as Old Babylonian times the goddess Nininsina was still imagined with the head of a dog, and over and over again nonhuman features vie with human ones in monumental representations: rays flare from the body of the sun-god, serpent heads peep out from the shoulders of Ningishzida next to his human head, grain sprouts from the body of the grain-goddess.

The approach to understanding of the numinous that led during the Early Dynastic period to attribution of external human form to divinity paralleled a similar new understanding of activity and function of the numinous in a human pattern, that of the "ruler." The growth and the progressive differentiation of society during Protoliterate times, and the accompanying development of governmental forms, had created a type of human ruler vastly more powerful than the early chiefs and village headmen, and hence the object of feelings of distance, reverence, dependence and awe. This evolving concept of the ruler made possible a new metaphor for understanding and expressing central elements in the numinous, its awesomeness and majesty. The term *en*, "lord," with implications of "manager who causes to thrive," is attested from the early part of the Protoliterate; its application to a god is first known from the late Protoliterate in the divine name En-lil, "Lord Wind." It soon came to be an integral part of many such names (Enlil, Enki, Enamash, Engara, Enduku, etc.). The term *lugal*, "king," especially leader in war, first occurs in the middle of the Early Dynastic period. It too was used as title for deities and forms part of divine names such as Lugalbanda, Lugalgirra, Lugalkisaa, Lugalmarada, etc.

The gods became a divine landed aristocracy with great manors (the temples), managed by a vast retinue of divine and human servants; as rulers of cities they became responsible for the social and political as well as the economic welfare of the community. At the end of the Early Dynastic period, at the word of Enlil, Ningirsu of Girsu agreed with Shara of Umma on their mutual boundary line, and later on, when Umma violated the line, Ningirsu declared war. The politically active gods were organized in a "primitive democracy" in which the highest authority was a general assembly meeting at Nippur under the presidium of An and Enlil to elect "lords" and "kings" from among the member gods, and to decide on the rise and downfall of dynasties and cities. The gods who were powers in nature had become powers in history: the numinous power in the phenomenon of birth, the "Lady Birth-giver," Nintu, became an officeholder endowed with the office (*garza*) of furthering birthgiving, an office conferred upon her by Enki; Dumuzi, the mysterious power in the ewe of begetting and of giving milk, became a divine shepherd whose office was to manage and look after cattle pens and sheepfolds, and so forth.

The full realization of distance between human and divine that flowed from the ruler metaphor, as well as the living sense of a mighty power of nature still inherent in the god, is shown in Gudea's prayer to Ningirsu:

> O my master Ningirsu, lord who sends the awesome waters,
> Potent lord, engendered by the Great Mountain,
> Warrior whom none can challenge,
> Ningirsu, I am to build you your house, but have no sign!
> Warrior, you have called for what is fitting
> But, son of Enlil lord Ningirsu,
> I cannot know what that means!
> Your heart, which lifts like the swell in midocean,
> Comes crashing down like great ebony trees,
> Which roars like the waters of a breech in a dike,
> Destroys cities like a flood,
> Which rushes at the enemy country like a storm,
> O my master, your heart, the onrushing waters of a breech in a dike,
> not to be restrained,
> Warrior, your heart, remote like the Heavens,
> How can I know it?

It affected deeply man's place in the scheme of things. Ruled by the gods, working on their estates as servant or field hand, he became the serf of the god, who might be harshly treated but could not be abandoned. As lord of the manor (the temple) the god was tied to his lands and people; hence the greatest crisis life could know was destruction of the temple, the threat of breaking forever the bond between god and man. Around this direst of all calamities centre the most important, most fervent and perhaps most profound expressions of Sumerian religious feeling, the public laments, designed to strengthen and repair the bonds that had become severed, to calm the god and induce him to undertake the task of reconstruction.

3. National Gods.—The last phase of ancient Mesopotamian

religion may be counted as beginning late in the Old Babylonian period and lasting to the end of Babylonian and Assyrian civilization. It is marked by the rise of two national gods, Marduk and Ashur, to positions of supreme power in the world of the gods, and reflects the eventual crystallization of Mesopotamia into the two rival national states, each under an absolute monarch. The old pantheon and religious framework generally remained relatively unchanged, but the emphasis had subtly shifted; power and decision were now centred in Marduk or in Ashur, the other gods acting as their agents or as intercessors with them. The strong feeling of unified central power found its expression in henotheistic tendencies; the various gods were seen as in essence one with aspects of a supreme god. We are told that Enlil is Marduk (as god) of lordship and counsel, Nabu is Marduk (as god) of accounting, Sin is Marduk (as god) illuminating the night, Shamash is Marduk (as god) of justice, Adad is Marduk (as god) of rain, etc. Similarly the other gods may be identified with parts of the body of Ninurta: his eyes are Enlil and Ninlil, the iris of his eyes Sin, his lips Anu and Antum, and so on. There is a recognizable drive to see the forces that govern the cosmos as basically one and unified.

The classical image of the god as ruler, responsible for defense against external enemies and for prosperity and order internally, sharpened in the late phase. The national character of Marduk and Ashur as supreme gods identified them closely with external national interests; through signs and omens they actively guided the policies of their countries, so that religion and politics became more inextricably linked than ever before. In the struggle of the Sargonids to subdue Babylon, cult and ritual were in the centre of the fray; Sennacherib even appears to have tried to transplant the New Year festival of Babylon bodily to Assyria, with Ashur as the chief figure rather than Marduk, and groups of fragmentary Assyrian texts testify to the use of astoundingly virulent religious political propaganda.

In internal affairs, divine concern with social order, questions of morality and ethics were prominent, dominating the image of the gods. The concept of the god as ruler—now given its special colour from the everyday experience of absolute monarchy—tended to produce a piety bordering at times on subservience and anxious avoidance of even the semblance of independent initiative: "Take not to heart matters of strength and power, seek Nabu and Marduk and let them kill your foes" is the advice Nabopolassar hands on to later rulers. In the private prayers that have survived the penitent crawls before the god in veritable orgies of self-abasement, pleading for mercy for sins he is not aware he has committed.

The utter dependence of man on the gods in all matters raises the question of the righteous sufferer. By Old Babylonian times it became general belief that all men had personal gods who watched over them and that—in contrast to what had been thought earlier—the personal god was easily capable of withstanding all demons and evil forces. Sickness or other ills meant therefore that the protective deity had turned away from his ward in anger or disgust, leaving him a prey to evil, and that the ward must have committed a ritual or moral sin to alienate his god. With time the emphasis shifted more and more to the latter type of sin, and elaborate rituals with penitential psalms were used to regain the good graces of the angered god or goddess. Out of this literature grew attempts to deal with the paradox of the righteous sinner, the pious and upright man who was yet allowed to suffer. The solution found was a humble realization of the limitation of human insight and human judgment; man lacks the larger perspective of the eternal gods.

B. Sumerian Pantheon

The Sumerian pantheon was exceedingly numerous—it seems to have contained some 3,000 to 4,000 deities—hence only a few of the more prominent gods can be considered here. This article concentrates on such as ranked as chief deity of a city and lists them in regional arrangement according to the location of their cult city.

1. Southeastern Marshes.—The marshes and lakes that in ancient times separated the inhabited areas of Sumer from the Persian gulf seem to have begun southeast of a line from Eridu (Abu Shahrain) in the desert west of Ur up to Nina (Surghul) in the southern part of the Lagash region. The deities worshiped in the cities located there all appear to represent powers vital to men who derived their livelihood from the marshes; they are powers in the waters and the reeds, in the birds and fishes, and they are seen in shapes drawn from the familiar forms of animal and vegetal life in the marshes. They belong to a single family, that of Enki in Eridu, and Enki himself was the figure among them who gave rise to stories and myths about how he organized the country and its economy, how he outwitted the goddess of the gravelly desert lands in the west, always with creative results. The deities of this group of cities, the early pantheon of the marshlanders, are:

1. Enki (Ea; *q.v.*), the city-god of Eridu, situated in antiquity on a lake or lagoon. He was god of the fresh water of rivers, lakes and marshes, was known for great wisdom, and the power of water to cleanse made him god of ablution and lustration magic. His earliest name and form seems to have been Abzu, "the Watery Deep," later seen as an opponent vanquished by him. His name Enki, "Lord of the Earth," probably has reference to the fertilizing power of the irrigation waters. As creator god his name was Nudimmud; as god of ablution magic he was usually called En-uru, "Lord Reed Bundle," after the reed bundles out of which was constructed the reed hut in which the rites were performed. In historical times he was generally envisaged in human form, but an earlier nonhuman form of the god survives in his emblem, the ibex, which often is depicted under his feet. Other emblems, also seemingly older nonhuman forms of the god, were a goat the body of which tapers into that of a fish, and a ram-headed curved stick. The Akkadians identified Enki with their god Ea, and in later times a variety of gods of special crafts were identified with him.

As father of Enki the texts mention the god of the wind, Enlil of Nippur; his mother was Enlil's housekeeper, Nammu. As Enki's father, perhaps to be understood as his grandfather, occurs sometimes also the god of the sky, An. Enki's spouse was Damgalnunna, "The Great Spouse of the Prince," whom the Akkadians called Damkina. The Janus-faced god Sha (Akkadian Usmu) served as his vizier.

Of the more noteworthy myths dealing with Enki may be mentioned the Tilmun myth, which tells how he engendered a great variety of deities, among them Uttu, the spider, goddess of weaving; the "Myth of Enki and Ninmah," which tells about the creation of man and of how human freaks came into the world through a contest between these two creator gods; and "Enki Organizes Sumer," which tells how Enki blessed the major cities of Sumer, arranged for the rivers, marsh and sea, and instituted agriculture and husbandry and other important features of the economic life of the country.

2. Asalluhe (Marduk), city-god of Ku'ar, in the general vicinity of Eridu. Asalluhe was active with Enki in rituals of lustration magic and was considered his son. His name, "Man-Drenching Asal," suggests that he was originally a god of thundershowers and corresponded in the marshman's pantheon to Ishkur in the herder's and Ninurta in the farmer's. His epithet *lu-he*, "man-drenching," also is applied to Ishkur. In the incantations he is regularly the one who first observes and calls Enki's attention to existing evils, perhaps in his role of thundercloud surveying the world from on high. He was later identified with Marduk of Babylon.

3. Dumuzi-abzu, city-goddess of Kinirsha in the southeastern part of the Lagash region. Dumuzi-abzu was the power for fertility and new life in the marshes. Her name means "the Quickener [of] the Young [in mother's womb] of the Deep," and she corresponds in the marshman's pantheon to Dumuzi in the herder's. She was considered a goddess in the Lagash region, but in the region around Eridu she was viewed as male—possibly due to influence from Dumuzi of the herder's pantheon—and as son of Enki.

4. Nanshe (or perhaps better Nazi), city-goddess of Nina (Surghul) in the southeastern part of the Lagash region. Goddess of fish and fishing, Nanshe was envisaged as dressed altogether in fish. Among her accomplishments was skill in interpreting

dreams, and an important hymn to Nanshe and many references in other texts stress her concern for equity and social justice. Her father was Enki, her husband Nindara, called the "tax-gatherer" of the sea.

5. Ninmar, city-goddess of Guabba, situated on the shore of a lake or lagoon in the southeastern part of the Lagash region. She seems to have been a bird-goddess, and her emblem, a bird, probably represents her original nonhuman form. She was the daughter of Nanshe and thus granddaughter of Enki.

2. Southern Orchards.—In the south, the region along the lower course of the ancient Euphrates from Erech past Ur, three different early economies and their gods came together. Cities of the marshlander's family of gods descended from Enki can be followed from Eridu and Ku'ar in this region over toward Nina in the east; cities of the herdsman's family of gods descended from Nanna in Ur show connection northward to cities in the central grasslands; and lastly there is a group of cities that have city-gods belonging to still a third family of gods descended from Ninazu. The gods of this group all have pronounced chthonian character as powers of the nether world, and several of them appear closely connected with trees and vegetation. Since the region in which their cities lie is one of the chief centres of date cultivation in the country, and seems to have been equally so in antiquity, it is perhaps not unlikely that they represent the pantheon of the early fruit growers and their settlements along the riverbanks, dependent on the powers for growth in the earth. To this group of deities belonged probably originally also Inanna in Erech as goddess of the storehouse of dates and her bridegroom Dumuzi-Amaushumgalana, the power for growth and new life in the date palm, both of whom were later absorbed in large measure into the pantheon of the herders. Inanna seems to have been the figure that gave rise to the major myths in the fruit growers' pantheon, such as the myth of Inanna and Shukallituda, which tells of the origins of shade-tree gardening, and the myth of Inanna's descent to the nether world, which seems to be a mythopoeic elaboration of the partly subterranean character of the storehouse. The gods of this group of cities are:

1. Ninazu, the city-god of Enegir, located on the lower ancient Euphrates between Larsa and Ur. Another city of his was Eshnunna (Tell Asmar) in the Diyala region. Ninazu was an underworld deity whose precise nature is not clear; the name seems to mean "Water Knower." He counted in Enegir as son of the queen of the nether world, Ereshkigal; a variant tradition made him a son of Enlil and Ninlil. His spouse, Ningirda, was a daughter of Enki.

2. Ningishzida, city-god of Gishbanda in the vicinity of Ur. Ningishzida was likewise a power of the nether world, where he held the office of "throne-bearer." Originally he seems to have been a tree-god, for his name appears to mean "Lord Productive Tree," specifically perhaps god of the winding tree roots, as he was originally envisaged in serpent shape. When he is pictured in human form, two serpent heads grow from his shoulders in addition to the human one, and he rides on a dragon. He was a son of Ninazu and Ningirda and was married to Ninazimua, "Lady Productively Grown Branch."

3. Damu, city-god of Girsu on the Euphrates in the general vicinity of Ur. Damu, son of Ningishzida and Ninazimua, was a vegetation god, especially, it seems, god of the sap that rises in trees and plants in the spring. His name means "the Child," and his cult—which seems to have been preponderantly a woman's cult—centred in rites of lamentation and search for the god, who had lain under the bark of his nurse, the cedar tree, and had disappeared. The search ended in the finding of the god, who reappeared out of the river. A particularly interesting feature of the Damu cult is that it recognized as incarnations of the disappearing and sleeping god all the dead kings of the 3rd dynasty of Ur and the early kings of the following dynasty of Isin. The cult of Damu influenced and in time blended with the very similar cult of Dumuzi the shepherd, at home farther north among the shepherds of the central grasslands.

3. Herding Regions.—In the south around the lower ancient Euphrates was a group of cities—Ur, Gaesh, Kiabrig, Larsa and Kullab—the chief gods of which seem to have been herdsmen's gods belonging to the family of Nanna. Farther north, in the centre of Sumer between the Iturungal and the ancient Euphrates, lay grasslands ringed around by the ancient cities of Erech, Bad-tibira, Umma, Zabalam and Bitkarkara, which likewise have city-gods connected with herding and belonging to the family of Nanna. The gods of these cities, however, especially Inanna and her young husband Dumuzi the shepherd, seem to be shepherds' rather than cowherds' gods. Lastly may be noted the two cities of Adab on the northern edge of the grasslands and Kesh, probably to be identified with Ishan Abu Salabikh, north of Nippur on the edge of the gravelly western desert, both cities of Ninhursaga, whose connections were with asses (onagers) and ass herding.

These groups of city-gods form, as it were, a herdsman's pantheon, a family of gods headed by Nanna of Ur—cowherds' gods in the south, shepherds' in the central grasslands. More loosely connected is the separate family of Ninhursaga to the north of them, the ass herders' gods. Characteristic for this pantheon of the herdsmen is a prominence of astral deities: Nanna, the moon; Utu, the sun; Inanna, the morning and evening star; and seemingly An, the sky. Deities of this group have forms derived from the world familiar and particularly meaningful to the herdsman: the animal of the herd or flock, the herdsman himself.

Southern Cowherds' Gods.—1. Nanna (Sin; *q.v.*), city-god of Ur and of the neighbouring Gaesh and god of the moon. His name Nanna may have designated him particularly as the full moon; another of his names, Ensun, "Lord Wild Bull," as the half-moon; a third, Ashimbabbar, as the new light. His original form, the moon, was sometimes visualized as a boat, sometimes as the horned crown of divinity, but most characteristically it was seen with the herdsman's eye as the horns of a great bull leading the herd of stars. In human form the god became a cowherd driving his herd over the sky, and in this form the Sumerian hymns most often present him. Nanna counted as son of Enlil and Ninlil; his spouse was Ningal.

2. Ninhar, city-god of Kiabrig in the region of Ur, probably toward the south. Ninhar was god of the thunder and rainstorms that make the desert green with pasturage in the spring and was envisaged under the shape of a mighty roaring bull. He was son of Nanna and Ningal and married to Ninigara, the "Lady of Butter and Cream," goddess of the dairy.

3. Utu (Shamash; *q.v.*), city-god of Zararim (Akkadian Larsa) in the south and of Sippar in Akkad. In both cities his temple was called Ebabbar. Utu was god of the sun and of justice and equity. His name means "sun," and his original form, the sun disk, seen through the eyes of the cowherd became the round head of a bison. This form survived as the god's emblem, "the Bison's Head, the emblem of Utu," mentioned by Gudea, and in the two crossed bison-headed figures often shown under his chair. When he is depicted in human shape his solar character usually is indicated by rays issuing from his body; often he holds in his hand another of his emblems, a saw. Utu was son of Nanna and Ningal and married to Shenirda. Their son was Shakan, god of goats and goat herding and of the gazelles and wild four-legged creatures of the steppe generally. As viziers of Utu occur the personified justice, Niggina, and equity, Nigsisa. The Akkadians identified their solar deity Shamash with Utu and their goddess Aia with Shenirda.

4. Ninsun, city-goddess of Kullab, an ancient city generally assumed to have merged into Erech but perhaps more likely identical with Larsa or with a part of it. Ninsun seems to be the divine power behind, and the embodiment of, all those qualities the herdsman hoped for in his cows—she is the "good cow," a "mother of good offspring that loves the offspring." As her name Ninsun, "Lady Wild Cow," indicates, she was originally imaged in cow shape, but in human shape she could also give birth to human offspring. Thus Gudea, whose personal goddess she was, is said to have been borne by Ninsun, "the good cow in its [form as] woman." In the cowherd's pantheon the good cow that loves the offspring became the type of the mother. The "wild bull" Dumuzi of the cowherds, as distinct from Dumuzi the shepherd of the shepherds, was her son whom she lamented—often very movingly—in the yearly ritual of lament for his death. As type of the

mother, Ninhursaga in the pantheon of the ass herder and, in less degree, Ninlil in the pantheon of the farmer are counterparts to her. Her husband was Lugalbanda.

5. An (Anu; *q.v.*), worshiped in Erech but not counted as city-god. An was god of the sky and father of all the gods. His name means "sky," and he seems originally to have been envisaged under the form of a great bull, a form later disassociated from the god as a separate mythological entity, the "bull of heaven," which he owned. The bovine imagery suggests that he belonged originally to the herdsman's, specifically the cowherd's pantheon, likely enough in view of the general predilection in that pantheon for celestial powers. As father of the gods An presides in divine assemblies and grants the highest offices, kingship and lordship. He is himself, more than any other god perhaps, the embodiment of majesty and supreme authority.

Central Grassland Shepherds' Gods.—1. Inanna (Ishtar), city-goddess of Erech and Zabalam (Bzeikh), also of Hursagkalamma (Uhaimir) in Akkad. Inanna appears originally to have been a personification of the powers in the storehouse for dates and to have belonged to the pantheon of the orchardman. She lives in Eanna, "the House of the Date Clusters," her name means "the Lady of the Date Clusters," her young husband is Dumuzi-Amaushumgalana, the power in the single great bud of the date palm, and their wedding takes place in the "storehouse." The reed bundles and rolled-up screen of the gate of the storehouse served as her emblem and original nonhuman form. As goddess of the storehouse more generally—the storehouse for wool, meat and dairy products—she seems to have been received early into the pantheon of the herdsman, where she appears as bride both of Dumuzi the shepherd and of "the wild bull" Dumuzi, and as daughter of the head of the herdsman's pantheon, Nanna. From this came probably her astral aspect as goddess of the evening and morning star, which led in post-Sumerian times to a reinterpretation of her name as "Queen of the Sky." As a personification of the storehouse awaiting union with the year's produce she early became typed—although the gods Shara and Lulal (Latarak) counted as her sons—as a young marriageable girl and bride rather than as wife and mother. Since the union of storehouse and produce is not a lasting one (stores are used up), her husband dies young soon after marriage. To her typing as a young marriageable girl she probably owes her role as incarnation of the rage of battle, for in early Sumer, as still among the Bedouins, it appears to have been the accepted function of young unmarried girls to encourage and egg on the young warriors in battle with praise and taunts. To her typing as unmarried girl she may possibly owe also her role of harlot and protectress of harlots. In the process of recasting the pantheon in human aristocratic pattern she became the type of the independent, willful and spoiled young noblewoman.

Of noteworthy myths about Inanna may be mentioned "Inanna and Shukallituda," which tells how the orchardman Shukallituda invented shade-tree gardening, found Inanna asleep in the shade under one of his trees and lay with her, and how she tried to find him afterward, sending various plagues upon the country but to no avail. The end of the story is not preserved. "The Descent of Inanna" tells how she attempted to take over rule of the nether world from her sister Ereshkigal, was changed into a cut of meat and held prisoner in the nether world, but was eventually revived through the agency of Enki and released on condition that she furnish a substitute to take her place. On her return, finding that her husband Dumuzi did not appear sorrowful enough at her disappearance, she delivered him up in a fit of jealous rage to substitute for her in the nether world. The myth "Inanna and the Powers of Office" tells how Inanna journeyed to Eridu, was granted a medley of offices and powers by Enki after a banquet in her honour when he was mellowed by wine, and left next morning to take them safely to Erech. She succeeded, although Enki seven times stopped the boat and tried to get the powers back. The myth was probably a *hieros logos* of a yearly ritual journey of the image of Inanna by boat to Eridu for purification and reappointment to divine office. "Inanna and Ebeh" tells of Inanna's conquest of the mountain range Ebeh, the present Jabal Hamrin. (*See* also ISHTAR.)

2. Dumuzi (Tammuz; *q.v.*), city-god of Bad-tibira (Madinah), is god of fertility and the production of new life. His name means "the Quickener of the Young [in Mother's Womb]" and he occurs in various forms: as Dumuzi-Abzu, "Dumuzi of the Watery Deep," in the marshman's pantheon; as Dumuzi-Amaushumgalana, "Dumuzi, the One Great Source [lit. 'mother'] of the Date Clusters," a deification of the heart of palm, the single great bud of the date palm, in the orchardman's pantheon, where Damu is a related figure; as "the Wild Bull" (*am*) Dumuzi, son of Ninsun, in the cowherd's; and as Dumuzi "the shepherd" (*sibad*), son of Duttur, goddess of the ewe, in the shepherd's pantheon. It is in the latter form (as the divine power to produce lambs and milk in the ewes in springtime) that he is city-god of Bad-tibira.

The cult of Dumuzi centres around two poles, the marriage of the god to Inanna, and the lamenting of his early death. The marriage was ritually consummated in a cult drama, a *hieros gamos*, in which the king took on the identity of the god, a priestess that of the goddess. It expressed different things in the various Dumuzi cults. In Erech the marriage of Inanna as goddess of the storehouse to Dumuzi-Amaushumgalana was essentially a harvest festival. It celebrated the relief of the community in knowing itself safely provisioned for a new year under the ritual image of the young girl finding security in marriage. In the marriage of Inanna to "the wild bull Dumuzi" of the cowherds in Nippur the rite was essentially a fertility rite of spring, the king's potency in the consummation of it being coincident with the shooting up of the flax, the grain and the verdure of the steppe.

The end of spring and of new life in nature, of the milking and lambing season, heralded the death of Dumuzi, the power who had produced it. His death was variously conceived. In the herdsmen's rites it was usually brought about by an attack on the young herdsman in the desert by raiders from the nether world. In the rites he was mourned by his bereaved mother, his sister and his young widow in laments that often reach great heights of beauty and compassion.

3. Shara, city-god of Umma and son of Inanna. The precise character of this god remains obscure.

4. Ishkur (Adad; *q.v.*), city-god of Bitkarkara, a city mentioned between Zabalam and Adab and perhaps to be identified with the modern site of Tell Jidr. Ishkur was god of the rain and thunderstorms of spring, so vital to the herdsman because the pasturage in the desert depends on them. As Ninhar, whom he greatly resembles, Ishkur was imagined in the shape of a great bull and was son of Nanna. When he is depicted in human shape he often holds his symbol, the lightning fork. As god of rain and thunder he corresponds in the herdsman's pantheon to Asalluhe in the marshman's and has the epithet *lu-he*, "man-drenching," in common with him. In the farmer's pantheon his counterpart is Ninurta. Ishkur's wife was the goddess Shala. He was identified by the Akkadians with their god of thunderstorms, Adad.

Gods of the Northern Ass Herders.—Ninhursaga (Belitili), city-goddess of Adab and of Kesh, is the goddess of the stony rocky ground, the *hursag*, as it is found in the mountains to the east and as it comes out in the vast gravelly and stony desert to the west, contrasting so sharply with the alluvial soil of Sumer proper. Particularly she is the power in the foothills and in the desert to produce wildlife, and especially the wild onagers of the western desert are her offspring. Her name Ninhursaga denotes her as the "Lady of the Stony Ground." Other names for her are Dingirmah, the "Exalted Deity"; Ninmah, the "Exalted Lady"; Aruru, the "Dropper" (*i.e.*, who lets fall in birth); and Nintu, "Lady Birth-giver." As the sorrowing mother animal she appears in a lament for her son, a young colt, but as goddess of birth she is not only the goddess of animal birth but "the mother of all children." In curses on evil-doing future rulers she may be asked to stop all birthgiving in the land. Her husband is the god Shulpae. Of their children the sons Mululil and Ashshirgi and the daughter Egime may be mentioned. Mululil appears to have been a dying god, comparable with Dumuzi and Damu, whose death was lamented in yearly rites.

4. Farming Regions.—The ancient cities situated north of the central grasslands and up into Akkad, and to the east in the northern parts of the Lagash region, have city-gods most of whom

show connections with cereals or agricultural implements or otherwise indicate that they belong to the world of the farmer with its characteristic values and forms. They belong to a single divine family, that of Enlil in Nippur, and may be assumed to have constituted the farmer's pantheon. Their most distinctive features seem to be a pronounced fierceness and warlikeness in the male gods, who tend to the type of the warrior, and a stress on chthonian aspects. The figure that occupied the myth-making fantasy most centrally in the farmer's pantheon was Enlil. Late in the myth-making period, on the verge of that of the epic, interest seems to have shifted to Enlil's son Ninurta. The gods of this group are:

1. Enlil, city-god of Nippur, god of the wind. His name Enlil designates him directly as "Lord Wind," but with time the form in which he manifested himself came to be viewed more particularly as the breath issuing from his mouth, his "word" or "command." The wind, in the eyes of the Mesopotamian farmer, is not only the raging, destructive storm but also, and as significantly, the moist reviving wind of the spring that brings the rains and makes desert and fields green. At harvest time when the grain is winnowed Enlil, the wind, cleans it. The grain is Ninlil or Sud, his wife, "the Princess of the Copper [winnowing] Pan," the daughter of the goddess of the varicoloured barley. In the divine assembly Enlil is enthroned on Duku, "the Pure Mound," apparently the mythological prototype of the storage pile covered with mats and with earth to hold them down. There are indications that Enlil had to go away to the nether world, that he sleeps "the treacherous sleep," and is reawakened by Inanna. Details of this side of his nature—presumably the disappearance of the pleasant winds of spring and early summer is involved—are, however, not clear.

Enlil was son of An and presided with him in the divine assembly, which met in the court Ubshuukkinna in Ekur in Nippur. As "king of all lands," he granted with An kingship and lordship. Enlil's word, the wind, was the executive agent of the divine assembly, carrying out its decisions. When the gods had decided on the overthrow of a city it was Enlil's word that blew as a storm against it, enveloped and overwhelmed it—his word "which as stormcloud lies massively grounded on the earth, its interior inscrutable, his word which up above makes the heavens tremble, which down below makes the earth quake, his word with which the gods destroy." This divine word is the image under which the destroying, conquering enemy hordes were seen; or rather, it represented the inner truth of what was happening, the deeper reality for which the enemy horde of actuality was incidental.

Myths about Enlil include the "Myth of the Creation of the Pickax," which tells how Enlil created this basic agricultural tool and used it to break the hard crust of the earth in Uzumua in Nippur, letting the first men grow forth from the earth like plants there; the "Myth of Enlil and Ninlil," which tells how Enlil raped Ninlil when he first met her and was banished to the nether world, how Ninlil followed him, how under various disguises he united with her again and how she conceived, besides Nanna, the moon-god, the chthonian deities Meslamtaea and Ninazu and still a third god whose name is only imperfectly preserved in the text. (*See* also BEL.)

2. Ninlil, city-goddess of Tummal near Nippur, where she was known as Egitummal, and of Shuruppak, where she was known as Sud. Ninlil is "the varicoloured ear [of barley]," goddess of the grain (particularly, perhaps, of the seed corn), and counts as the daughter of Haia, god of the stores, and Ninshebargunu, "Lady varicoloured Barley," the goddess of the ripening barley, a form of the goddess Nissaba. The goddess Ezinu of the green barley issued from the seed corn seems to have been Ninlil's daughter. (*See* also BELIT.)

3. Nissaba, city-goddess of Eresh on the ancient Euphrates not far upstream from Erech, was goddess of the grasses generally, including the reeds and the cereals. As goddess of the reeds and provider of the reed stylus of the scribe she became the patroness of writing and the scribal arts, particularly of accounting.

4. Ninurta, city-god of Girsu (Telloh) in the Lagash region, where he was known by his name Ningirsu, "Lord of Girsu." Ninurta was the farmer's version of the god of the thunder and rainstorms of the spring. Since it is the early rains that melt the snow in the mountains and swell the rivers, he was also the power in the floods of spring; and since it is the rains and the general humidity in the air in spring that make the ground soft enough to be broken by the plow, he is also god of the plow and of plowing, much as his father Enlil is god of the older implement, the pickax. Ninurta's earliest name was Imdugud, which means "Rain-Cloud," and his earliest form was that of the thundercloud, envisaged as an enormous black bird floating on outstretched wings roaring its thunder cry from a lion's head. With the growing tendency toward anthropomorphism the old form and name were gradually disassociated from the god as merely his emblem; enmity toward the older inacceptable shape eventually made it evil, an ancient enemy of the god, a development culminating in the Akkadian myth about it as Anzu. The preferred names for the new human form of the god tended to be colourless epithets like Ningirsu, "Lord of Girsu," in Girsu.

Ninurta was the son of Enlil and Ninlil and was married to Bau, in Nippur called Ninnibru, "Queen of Nippur." A major festival of his, the *gudsisu* festival, marked in Nippur the beginning of the plowing season.

Myths about Ninurta are first of all the epic *Lugal-e*, which depicts the god as the type of the king as young leader of raids and wars. It tells of his battle with the rival king of the plants and the stones, the monster Asakku, in the mountains; his victory; his construction of a rocky ridge, the *hursag*, to regulate the irrigation supplies of Sumer; and of how he gave this ridge to his mother Ninlil when she paid him a visit after his victory (hence her name Ninhursaga, "Queen of the Hursag"). Lastly it recounts his judgments on the stones after his victory, judgments in which he assigned to them their various characteristics and uses. A second myth about Ninurta tells of his return to Nippur after victory in battle. An Akkadian myth deals with his victory over Anzu—his own earlier form of Imdugud, which now takes the place of Asakku as his opponent—and regains from it the tablets of destiny which it had stolen from Enlil.

5. Bau, city-goddess of Uruku in the Lagash region, and, under the name Nininsina, "the Queen of Isin," city-goddess of Isin, south of Nippur. Bau seems originally to have been goddess of the dog and her name, Bau, to have constituted an imitation of the dog's bark, as English "bowwow." As Nininsina she is till late envisaged with a dog's head, and the dog is her emblem. She became—probably because the licking of sores by dogs was supposed to have curative value—a goddess of healing. Her father was An, her husband Pabilsag, another name for Ninurta/Ningirsu. The Akkadians called her Gula (*q.v.*) or Ninkarrak as well as Bau.

6. Meslamtaea (Nergal; *q.v.*), city-god of Cuthah in Akkad. His temple in Cuthah was called Emeslam or Meslam, "Luxuriant Mesu Tree," and the god's name Meslamtaea, "He Who Issues From Meslam," indicates perhaps origin as a tree-god, which would agree with his general chthonian character. He was son of Enlil and Ninlil and appears in hymns as a warrior and so like Ninurta as to be almost indistinguishable. One difference, however, is that the weapons of Meslamtaea seem frequently to be turned against his own people and their herds, whom he kills as the divine power in the great plagues that so often swept ancient countries. Another name of Meslamtaea, Nergal, designates him as ruler of the nether world and as spouse of its queen, Ereshkigal. This may not have been original with the god, since other gods are mentioned as Ereshkigal's spouse in the older tradition, and since an Akkadian myth explicitly tells how he came to occupy that exalted position, the "Myth of Nergal and Ereshkigal."

C. Akkadian Pantheon

The gods worshiped by the Akkadians when they infiltrated Akkad are very largely unknown, but some idea of what the Akkadian pantheon was like can be gained from divine names occurring as part of Akkadian personal names of the period of the dynasty of Agade and just before. They show the presence of a not very clearly defined major god Il and of the astral triad Sin, god of the moon; Shamash, deity of the sun, seemingly a goddess; and Ashtar, later Ishtar, goddess of the morning and

evening star. The deities of this triad were identified with the Sumerian deities Nanna, Utu and Inanna respectively and merged into them.

A relatively large number of goddesses devoted to raids and battle are present: Anuna, "Skirmish," and Anunitum, "She of the Skirmish"; Inin, "Skirmishing"; Irnina, "Victory." Here belong perhaps also Shilabat, "She is a Lioness," and Shiduri, "She is My Fortress." All these figures tended in time to blend into that of Ishtar.

Lastly there was a group of deities of the thunder and rainstorms of the spring, similar to the Sumerian Ishkur and Ninurta. Most of these, it is perhaps worth noting, became city-gods: Dagan, seemingly a god of storm and rain, is the city-god of Tuttul on the Euphrates. Zababa in Kish seems to have belonged to this type also. Aba in Agade is known mainly as warrior and god of war. Tishpak, who replaced Ninazu as city-god of Eshnunna, was perhaps originally a rain-god; his name may mean "the Down-pouring One." To the gods of rain and thunder belongs also Adad.

Of frequent occurrence is Ea, probably a river-god, who was identified with Sumerian Enki. The gods Malik, "the Counsellor," the chthonian god and goddess Irra and Allatum, and the goddesses Mama and Ishhara may at least be mentioned.

Generally speaking, the early Akkadian pantheon with its prominent astral triad of moon, sun and morning and evening star, and with its gods of the rain and thundershowers that bring out grass and pasture in the spring, seems fairly close to the Sumerian herdsman's pantheon and constituted itself very probably the indigenous pantheon of pasturing nomadic tribesmen.

D. Assyro-Babylonian Pantheon

To the end of Mesopotamian civilization the long lists of gods of the Sumerians continued to be copied and hymns to ancient Sumerian gods in the Sumerian language continued to be sung in the temples; none of the old gods was deliberately discarded. Yet, as in the 2nd millennium, when the two national states of Babylonia and Assyria arose, decided changes in emphasis and attention took place. Two young autocrats, Marduk of Babylon and Ashshur (Ashur) of Assyria, came to occupy the foreground and the older gods receded, still prominent and worshiped but seen less and less as primary sources of power. The major figures besides Marduk and Ashur were in later time Marduk's son Nabu (*q.v.*) of Borsippa, god of the scribal art and secretary in the assembly of the gods, and the older gods An, Enlil, Ea (Enki), Sin (Nanna), Shamash (Utu), Adad (Ishkur), Ishtar (Inanna), Ninurta—especially in Assyria—and Nergal. Of these Marduk and Ashur may be discussed in more detail.

1. Marduk.—Marduk, the city-god of Babylon, would seem to have been in origin a Sumerian god and go back to times when Akkad and Babylon were both still Sumerian, for both Marduk's own name and the names of his temple Esangila and its ziggurat Etemenanki are Sumerian. His original character was probably —like that of Asalluhe with whom he was identified and with whom he shows intimate relation—that of a god of thunder and rainstorms, and he seems, like Asalluhe and other gods of thunder and rainstorms, to have been imagined under the outer form of a bull, the bellow of which was heard in the thunder. His weapons, with which he gained victory over the forces of primeval chaos, were the bow and arrow, probably representing the lightning shot by the god of thunder, and his symbol is an arrowhead or head of a spear. In the course of time, by a process of syncretism, Marduk came to absorb a number of other, originally independent gods such as, for example, the god of spells, Tutu; the god of irrigation, Enbilulu; the grain-gods Ezinu and Gil; and many others. As a result Marduk presents a highly complex and opaque figure. In later time the god is usually depicted in human shape and accompanied by a dragon known as the *mushhushshu*. Marduk was the son of Ea and Damkina (Enki and Damgalnunna) and was married to the goddess Sarpanitum. Around the figure of Marduk centres the Babylonian creation story, a myth that in its kernel (the battle between the god of the thunderstorm and the god of the sea) does not really fit in a Mesopotamian natural setting and seems to have been borrowed from western myths (*see* Creation, Myths of).

The most important festival for Marduk, the New Year festival in the spring, was in its essence a re-enactment and reaffirmation of his original achievement of reducing the universe to order. The first days of the month of Nisan were given over to preparations and purification of the temples for the festival. On the fourth the whole of the creation myth was recited before the god. Of the fifth, when Marduk's son Nabu arrived from Borsippa, the festival proper began with a ceremony of reinvestiture of the king. The high priest took the royal insignia away from the king, smote him on the cheek and made him kneel before Marduk to say a prayer in which he assured the god that he had done no wrong but had ruled properly. The high priest then assured him of the god's favour, restored to him the insignia of office and struck his cheek a second time. If the blow brought tears to the king's eyes it was a sign that the god was friendly; if not, that he was angry. On the eighth Marduk took his seat amidst the assembled gods in the chamber of destinies, Duku, for the deciding of destinies, probably a re-enactment of the divine assembly in which Marduk was made king. On the tenth followed a great procession and journey by boat out of town to the *akitu* temple, the king leading Marduk. This seems to reflect the march to battle with Tiamat, as related in the myth. On the 11th the assembled gods again paid homage to Marduk in the chamber of destinies, presumably a re-enactment of the celebration of Marduk's victory, his feats of organization and his election as "lord" by the gods. On the 12th day the festival ended and the gods returned to their temples. (*See* also Marduk.)

2. Ashur.—Ashur, the city-god of Ashur and national god of Assyria, is in origin and essence a most elusive figure. Possibly he was in the beginning merely a *numen loci* of the city that shares his name. In later times, from Shamshi-Adad I onward, there appear to have been strong tendencies to identify him with the Sumerian Enlil, and not only titles of Enlil but deities associated with him and cult places of his in Nippur are duplicated in Ashur in Assyria. Still later, under Sargon II, there were tendencies to identify Ashur with Anshar, the father of An in the creation myth. Under Sennacherib abundant materials testify to deliberate and thorough attempts to transfer to Ashur the primeval achievements of Marduk as told in the myth, as well as the whole ritual of the New Year festival of Babylon—attempts that clearly have their background in the political struggle with Babylonia. In view of this it may be asked whether also the earlier tendency to identify Ashur with Enlil may not have had mainly political motivation and to have implied a political program of domination over Sumer and Akkad rather than any actual affinity of nature and function between the two gods. As a consequence, the image of Ashur seems to lack all real distinctiveness and contains little that is not implied in his position as the city-god of a vigorous and warlike city that became the capital of an empire. He grants rule over Assyria, supports Assyrian arms against enemies and even receives detailed written reports from the Assyrian kings about their campaigns. He appears a mere personification of the interests of Assyria as a political entity, with little character of his own.

E. The Individual and the Powers

During the classical period Mesopotamian religion underwent a process of structuring along the lines of political organization; all of the cosmos became a great state in which the gods held the supreme offices and wielded the supreme authority. In seeking to understand the viewpoint and position of the individual worshiper it is well to keep this in mind. The individual had direct and personal relations mainly to his own personal god, the power who took a personal interest in him and his fortunes, whom he worshiped in a daily private cult, to whom he brought his immediate personal problems, and whom he occasionally badgered if he did not think he was properly taken care of. The major gods were more like high officials in the state, whom one might see on official occasions—*in casu* at the great festivals—but with whom an ordinary citizen had few personal dealings.

This does not mean, however, that the relationship to them and dependency on them was any less real and important. As the government is responsible for the smooth running of a nation's economy, for defense and for internal peace, law and order, so the gods were the responsible powers for order in nature, for peace and prosperity in social life. Direct contact with the higher gods the individual would seek mainly when he felt himself harmed, much as a citizen in such cases will turn to the government and the courts for protection. Such contacts were sought by the individual in cases of illness, attacks on him by the lawless demons of disease, when help from the higher gods was needed to restrain the demons and to pacify and reconcile the personal god who had turned from the man in anger, exposing him to attack.

Not only in illness but in every situation of anxiety and uncertainty the individual was likely to seek divine guidance through omens, that he might know the will of the gods. And such guidance was sought assiduously, even by the greatest rulers and kings, in all matters of import. The state was directly ruled in its major policies by divine instructions.

The religious framework thus affected and conditioned life in ancient Mesopotamian society intensely and on all levels. It may be assumed that, as in most societies, the majority of men in ancient Mesopotamia had normal aptitude for, and sensitivity to, religion and religious values. Occasional individuals lacking in such normal sensitivity, who could see in religion only meaningless restrictions on their personal inclinations, will of course have been found, perhaps especially among the slaves and brutalized poor. To balance them the civilization seems to have had an unusually large number of highly sensitive minds, religiously creative poets, thinkers and priests. Mesopotamian religious literature at its best is the literature of a people highly gifted in religion, capable of profound religious insights and of finding profound and moving expression for them. (T. JA.)

VI. LANGUAGE AND LITERATURE

A. LANGUAGE

The language of ancient Babylonia and Assyria—Assyro-Babylonian, or Akkadian—belongs to the Semitic language family and is customarily set apart as East Semitic from its cognates, the West Semitic languages. It is the earliest recorded Semitic language and hence of considerable importance for comparative linguistics. Records of Akkadian extend in time from *c.* 2400 B.C. into the 1st century A.D., and in space from Persepolis to Egypt. The writing system for Akkadian was borrowed from Sumerian, the world's oldest written language, and though Akkadian replaced Sumerian as a spoken language in the 3rd millennium B.C., Sumerian continued in written usage almost to the end of the life of Akkadian.

These languages are discussed in the separate articles AKKADIAN LANGUAGE and SUMERIAN LANGUAGE.

B. LITERATURE

1. Word Lists.—Among the pictographic tablets of the Protoliterate period there are a few that are not accounts but rather lists of gods. Since the sequence of the names is essentially the same as in later lists, these are the first examples of a kind of literary composition that became very important throughout Babylonian history. From the earliest stage of the Early Dynastic III period (1st dynasty of Ur) came numerous lists of gods and of common words found at Tell Fa'rah, the ancient Shuruppak. The listing of words arranged in certain categories was one branch of Babylonian scholarship. The categories were determined by graphic elements common to a group of words, either determinatives like *dingir*, "god," *gish*, "tree," "wood" (also used for implements and objects made of wood), *na*, "stone," etc.; or parts of simple and composite word signs, such as *ur*, "dog," alone and in *ur-makh*, "great dog" (*i.e.*, lion), *ur-ge*, "domestic dog," and so on. Unilingual Sumerian word lists, which were copied as late as the Old Babylonian period, show that the primary purpose of these lists was encyclopaedic: the systematic collection of all possible words and concepts. The practical purpose of providing pupils with a "spelling guide" may also have been served by these lists.

From Old Babylonian times onward Akkadian translations were added to the lists, which thus became vocabularies. The commonest type of vocabulary was arranged in three columns: the word sign or signs in the centre; the Sumerian pronunciation, expressed by simple syllables, in the left; and the Akkadian equivalent, again spelled syllabically, in the right column. As time went on, many different types of vocabularies were developed, based on different principles of listing; *e.g.*, lists of complex word signs only, of names of professions, of gods, etc. Some vocabularies were provided with a commentary (*i.e.*, with a fourth column added to the normal three) explaining the Akkadian word with a commoner synonym. Unilingual Akkadian synonym lists in two columns also were compiled. Such vocabularies of various types remained in use until the end of Babylonian scholarly activity. There is no doubt that they were used in the schools, especially for the learning of Sumerian once this language had become a dead, literary language. Grammatical paradigms of Sumerian declension and conjugation with Akkadian translation served the same purpose. Listings of legal phrases, including paradigms of the verbs occurring in them, were meant for the use of public scribes who drew up contracts for individual patrons; they begin to occur in the Isin-Larsa period, in which individual legal documents became necessary with the development of an economy based on private property and enterprise. However, the encyclopaedic character of the lists and vocabularies is manifest from their composition and should not be overlooked.

2. Historiography.—The earliest royal inscriptions are simple dedications of buildings or objects of the type "To god X has A, son of B, king of the city Y, given this vase" or "built this temple." A little later, but still in the Early Dynastic period, the occasion for such dedication was mentioned in a sentence introduced by the phrase "on the day when . . . ," and this gave an opportunity to mention a ruler's victories or other deeds. More elaborate royal inscriptions, enumerating many campaigns or various buildings with great detail, developed out of this original pattern; for a long time they retained the external form of introducing references to historical events by "when" and those to the building activities of a king by "then."

The Assyrians further developed this pattern into what is known as "annals"; *i.e.*, detailed accounts of a king's military exploits for each year. Some of the annals, instead of counting years, count "campaigns." This literary form first appeared in Middle Assyrian times and remained in use in Assyria until the downfall of the empire, but was never imitated in Babylonia.

Besides royal inscriptions, which are styled as the words of the ruler and tell of his deeds in the first person, there was also some historiography in an "objective" style—*i.e.*, in the third person. The Sumerian as well as the Assyrian king lists contain, besides the simple enumeration of kings with their regnal years, some short additions telling the most outstanding facts about some of the rulers listed. Whereas some of these entries are based on popular, sometimes even mythological stories (*e.g.*, "Etana, the shepherd, who rose to Heaven" in the Sumerian king list), others give historical information based either on reliable memory or on good sources (*e.g.*, passages on Shamshi-Adad and other kings in the Assyrian king list). The more practical aspects of the king lists are discussed above, under *History;* in connection with historiography, however, it is worth noting that the Sumerian king list by its nature reflects a certain historical concept. There was one "kingship" that came from the gods and rested with one city after another. This passing of the kingship later was explained on religious grounds: the concept of bad rulers who were punished by losing the kingship and of good rulers who were rewarded with it is the next step, reflected in certain literary texts. This concept, in turn, was developed into that of times of bliss and of distress following one another in the past and (according to late texts) also expected for the future.

Another form of nonpersonal historical account, the chronicles, is known mainly from Babylonia, though not entirely absent in Assyria. Chronicles concerning early kings are based in part on

anecdotes or popular tales, in part on good tradition. Beginning with the period of Assyrian domination over Babylonia and continuing to the conquest of Babylon by Cyrus there are chronicles based on contemporary records, listing the events of every year, often by the month and day.

3. Chronological Works.—The system of dating was different in Babylonia and Assyria, and in the former it was different as between earlier and later times. In the early periods of Babylonian history, down to and including the 1st dynasty of Babylon, each year was named after an outstanding event. From the Kassite dynasty to the Seleucid period dates were expressed by regnal years. In Assyria there was the system of naming each year after a person who held the office of *limmu* or eponym; the king himself was usually *limmu* for one year, whereas in the other years of his reign certain high officials, such as the vizier and provincial governors, held this office. It is obvious that the two systems of years named after events and of years named after eponyms were usable only if records of their sequence were kept. Such "date lists" and *limmu* lists actually have been found, though unfortunately not of all periods. The dating by regnal years necessitated the keeping of king lists, and king lists also were composed during the period of dating by events in Babylonia, as well as in Assyria at all times in addition to the *limmu* lists. It may be assumed that the parts of the king lists that deal with historical times were based on original date lists in Babylonia and on *limmu* lists in Assyria. The difficulties that confront the historian who wants to use these lists are due, on the one hand, to the accident of loss and preservation and, on the other, to the habit of listing contemporary and overlapping dynasties as though they were successive. From the viewpoint of literary and intellectual history these lists, though answering practical needs, reflect a tendency toward systematization comparable to that underlying the word lists.

4. Literary Texts.—The discovery and publication of literary texts from Nippur revealed the existence of an extensive Sumerian literature. Although the extant copies were produced for the most part in the Old Babylonian period, these Sumerian texts must have first been written earlier, when Sumerian was still a living language—a few can be dated to the 3rd dynasty of Ur—and some of them may have existed in oral tradition even earlier. Among these literary texts there are myths, epics about the deeds of early kings, lamentations (the *Lamentation Over the Destruction of Ur* must have been composed after the sack of that city at the end of the 3rd dynasty), hymns and wisdom literature (proverbs).

The Old Babylonian period, during which these Sumerian works were copied in the school of Nippur, also produced a literature in Akkadian. Although many of its works are known in later copies only, Old Babylonian fragments have been found of some (*e.g.*, of the Gilgamesh epic), while other compositions may be dated to the same period on the basis of the particular Old Babylonian dialect in which they are written. One of the latter is the *Epic of Creation,* which tells the story of how Marduk, the city-god of Babylon, slew the monster Tiamat and created the world out of her body, a deed for which the other gods rewarded him by granting him universal rule (*see* CREATION, MYTHS OF).

The stories about Gilgamesh provide a good example of literary history. Among the Sumerian works there is no "Gilgamesh epic" but rather several independent stories about the ancient king of Erech; some of them describe his wars with rival rulers, whereas others are more mythological, dealing with his slaying of the monster Huwawa or his visit to the nether world. The oldest copies of the epic proper come from the Old Babylonian period and are in Akkadian. Accordingly, the Gilgamesh epic as we know it is a creation of the Babylonians rather than the Sumerians. This epic incorporated some, but by no means all, of the individual Sumerian stories, and introduced a new motif, Gilgamesh's quest for immortality after the death of his friend, Enkidu. The classical form of the epic is known mainly from copies found in the library of Ashurbanipal at Nineveh; this version probably was written in Middle Babylonian times. An earlier version was read over a wide area and translated into foreign languages. From the 14th and 13th centuries there are fragments in Akkadian discovered at Megiddo in Palestine and in the Hittite capital, and in the latter place fragments were found of a Hurrian and a Hittite version of the epic. This spread of the most outstanding Babylonian work is important for the understanding of the history of epic literature as a whole (*see* GILGAMESH, EPIC OF). During the 14th and 13th centuries mythological epics were written by the Hittites as well as by the Semitic people of Ugarit (Ras Shamra in north Syria). Whereas the Ugaritic myths have a bearing on Old Testament studies, some of the Hittite texts are comparable in content to the *Theogony* of Hesiod; these Hittite texts, in turn, reflect the Babylonian concept of a succession of kings among the gods, which was transmitted to the Hittites by the Hurrians. Although many of the details require further study, it is clear that western literature received some influence from Babylonia through these channels.

5. The Canon.—Babylonian literature as represented in the library of Ashurbanipal consists of a collection of standard works that has been called the canon. In this collection the individual literary works had a well-established text; works that, because of their length, covered more than one clay tablet were divided into several tablets, each of fixed length, so that, for example, the 11th tablet of the Gilgamesh epic begins and ends with the same verse in all copies. Apart from the epics the canon contained the vocabularies and other lists, collections of omens of various kinds, of prayers and incantations with their ritual, etc. In those cases where Old Babylonian versions of texts are available, they differ from the canonical form. The canon, therefore, must have been established in Middle Babylonian times, between the end of the 1st Babylonian dynasty and the rule of the Assyrian Sargonids. The fact that works of Babylonian literature copied by the Hittites in the 14th and 13th centuries show a precanonical text gives some further indication that the canon did not exist before that time. Some Old Babylonian works of literature were not taken into the canon; other works were composed after it had been established and also remained outside the canon. *See* above, *Civilization: Intellectual Achievements. BABYLONIAN CAPTIVITY, the name generally given to the deportation of the Jews to Babylon by Nebuchadrezzar. Three separate occasions are mentioned (Jer. lii, 28–30). The first was in the time of Jehoiachin in 597 B.C. After 11 years a fresh rising of the Judaeans occurred; Jerusalem was razed to the

ground, and a further deportation ensued. Finally, five years later, Jeremiah records a third captivity. The various captivities form the material of several of the psalms. (*See* JEWS.)

The term Babylonian captivity also has been used metaphorically to describe the exile of the popes to Avignon (1309–77). *See* PAPACY: *The Papacy in Avignon.*

BABYLONIAN LANGUAGE: *see* AKKADIAN LANGUAGE.

BACĂU, a town in eastern Rumania and administrative centre of the Bacău region, lies near the confluence of the Bistrița and Siretul rivers and on the main railway from Bucharest to Chernovtsy, U.S.S.R. Pop. (1963 est.) 65,763. First mentioned in documents in 1408, Bacău is a centre of heavy industry and has factories producing oil field equipment, building materials, paper, textiles, footwear, leather and timber goods. It has a state theatre, a symphony orchestra and a regional museum.

BACĂU region, on the eastern slope and foothills of the Carpathian mountains, is drained by the Bistrița, Trotuş and Tazlău flowing southeast into the Siretul. Pop. (1963 est.) 1,103,964. Area 13,400 sq.km. (5,174 sq.mi.). The region is oil bearing, with workings at Moineşti, Lucăceşti, Solonț, Tețcani and Tazlau de Sus, and yields about 20% of the crude oil produced in Rumania. There are refineries at Dărmăneşti and Borzeşti. At Bicaz on the Bistrița, there is a hydroelectric plant. Other modern industrial developments include the production of chemicals at Borzeşti; fertilizer at Roznov; and man-made fibres at Săvineşti. Agriculture and animal husbandry are secondary, only about 27% oi the region consisting of arable land.

BACCARAT, a game of cards of French origin. In its original form, baccarat banque, it is played only in gambling casinos on the European continent, and even there it is not so popular as its variant, *chemin de fer,* which is a medium of high-stake gambling in the eastern United States and England.

Legend places the origin of baccarat in the 15th century, and it is true that similar games are described in *L'Académie de jeu* of the Abbé Bellecour (1768), but its popularity in France dates from the 1830s and in England it was known and played shortly thereafter.

Method of Play.—Baccarat is played with several 52-card packs of cards—at least three in baccarat banque, usually six in *chemin de fer*—all shuffled together. The player's object is to have, in two or three cards, a count of 9 or as nearly so as possible; court (face) cards and tens each count 0, each other card counts its face value. Only the final digit is significant; if the two cards in a hand are eight and five, the count is not 13 but 3, so that the highest possible count is 9.

In baccarat banque a banker is selected; usually an auction is held, and the banker is he who undertakes to supply the largest bank (fund with which to accept bets). The banker deals the cards, one at a time, face down, in order to his right, to his left and to himself, until he has dealt three hands of two cards each. Rules of precedence established for the game designate one player on each side to play the hand against the banker. Prior to each coup, punters (players against the bank) may bet on either the right or the left hand or on both (*à cheval*) to beat the banker's hand. The banker is not responsible for the payment of bets in excess of the announced value of his bank.

The deal completed, each active player looks at his cards. A count of 8 or 9 is a natural and wins without contest, except from another natural. A natural 9 wins at once from a natural 8. With any lower count, each player in turn either may stand (saying *non*) or may say *carte,* whereupon the banker gives him one additional card, face up. The banker may stand or take another card after seeing the additional cards, if any, he has given to his opponents.

The full hands are then compared, and the banker settles separately with each side, paying the amount bet on a side with a higher count and collecting all bets on a side with a lower count. When there is a tie, bets on that side are called off.

Elaborate rules for baccarat are established by the casinos at which the game is played and often are made available in printed form to patrons. The various codes are nearly uniform, though there are some differences. Invariably, no part of the bank plus its winnings may be withdrawn unless the banker retires. Most casinos charge 5% of the amount of each bank as a fee.

Chemin de fer may be played by any number of persons. The first banker is decided by lot or by auction; thereafter, whenever the banker loses a coup, or voluntarily relinquishes the bank, the right to be banker passes to the next player in rotation (to the left in the U.S., to the right in Europe). Each banker states the amount of his bank; it may be any amount. The house charges $2\frac{1}{2}$% of each bet as its fee, collecting from the winners of the bet. Thus a player who bets \$5 and wins must pay 25 cents, $2\frac{1}{2}$% of the \$5 he bet plus the \$5 he won.

The cards are dealt from a dealing box, called a shoe. Only two hands are dealt. The hand opposing the banker is played by the punter who made the largest bet against him.

Banco.—Always in *chemin de fer,* and often in baccarat, any punter is permitted to cry "banco," meaning that he bets the entire amount of the bank; whereupon all smaller bets must be withdrawn in deference to him. The right to banco, if two or more claim it, is in order of precedence.

Rules of Play.—A punter must stand on 6 or 7; must take a card with 4 or lower; and has the option (*à volonté*) with 5. In many clubs and casinos these restrictions do not apply to a player who goes banco.

The banker is not so restricted, though some casinos do not permit him to vary from the procedure that is best mathematically. A croupier is provided by every casino to advise the banker. In *chemin de fer,* or in baccarat as against either opponent considered separately, the banker's best play is as follows. If opponent stands: banker stands on 6 or 7, draws to 5 or under. If opponent draws an ace, face card or ten, he stands on 4; nine, he stands on 4, optional to stand or draw with 3; eight, he stands on 3; seven or six, he stands on 7; five or four, he stands on 6; three or two, he stands on 5. In each case, banker stands on any higher number and draws to any lower number.

In baccarat, however, the banker must consider his best chance of winning a net amount. Suppose, with equal bets on the two sides, the left stands and the right draws a ten. The banker will draw to 4, though it decreases his chance of winning on the right, for by standing he would surely lose to the left. But if the bets on the left total only 50 chips, and the bets on the right 200, the banker will stand on 4, relinquishing the same bets to increase his chance of winning the large bets. The croupier must commit all such combinations, of which there are hundreds, to memory.

Baccarat has a large literature, most of it in French. The mathematical theory governing skilful play is explained in *Encyclopedia of Games,* by Emanuel Lasker (1929). (A. H. MD.)

BACCELLI, GUIDO (1832–1916), Italian physician and public official whose researches on malaria gave an impetus to the reclamation of the Roman marshes, was born at Rome on Nov. 25, 1832, and attended the University of Rome, where he became assistant professor of medical jurisprudence in 1856 and later professor of clinical medicine. In 1874 he was elected deputy for a division of Rome, which he represented until his death in Rome on Dec. 10, 1916. Baccelli's career in governmental affairs also included service as minister of public instruction and as minister of agriculture.

BACCHANALIA, the Latin name for the unofficial Hellenistic mysteries of Bacchus (Dionysus). They were introduced into Rome from lower Italy by way of Etruria and were held in secret, attended by women only, on three days in the year. Subsequently, admission to the rites was extended to men, and celebrations took place five times a month. The evil reputation of these festivals, at which the grossest debaucheries took place and all kinds of crimes and political conspiracies were supposed to be planned, led in 186 B.C. to a decree of the senate—the so-called *Senatus consultum de Bacchanalibus,* inscribed on a bronze tablet discovered in Calabria in 1640 and removed to Vienna—which prohibited the Bacchanalia throughout Italy, except in certain special cases. But, in spite of the severe punishment inflicted upon those implicated in the criminal practices disclosed, Bacchanalia were not suppressed in the south of Italy for a very long time. *See* also DIONYSIA; DIONYSUS.

BACCHUS (BACCHOS), a Thracian name of the god Dionysus. *See* DIONYSUS.

BACCHYLIDES (*c.* 510 B.C.–?), one of the most famous Greek lyric poets, was born at Iulis, in the island of Ceos, about 510 B.C. His father's name was perhaps Meidylus; his mother was the sister of Simonides, also a great lyric poet. Few of his poems are datable; of those that are, the earliest must have been composed in, or soon after, 476, and the latest in, or soon after, 452. He was thus active at the same time as Pindar, and anecdotes preserved by the medieval commentators on Pindar suggest that Pindar was bitterly jealous of him. The date and place of his death are unknown; B. Snell has suggested that one of his poems (xvi) shows acquaintance with Sophocles' *Trachiniae*, but since the date of the *Trachiniae* is itself uncertain (though most scholars now would put it after the *Antigone*, produced in 442 or 441), this suggestion is of little help to the chronologer.

Quotations from and allusions to Bacchylides' work in ancient writers are very few. In the last edition of T. Bergk's *Poetae Lyrici Graeci* (Leipzig, 1882) he has 26 pages, compared with his uncle's 154. However, in 1896 the British museum acquired over 200 papyrus fragments, said to have been found by Egyptians in a tomb at Meir in the Faiyum, which proved to contain poems by Bacchylides; F. G. (later Sir Frederic) Kenyon, in his first edition of 1897, was able to restore, in whole or part, some 20 poems of which 14 were epinician odes (odes celebrating victory) closely comparable with those of Pindar, and the remainder choral poems of a type which could be classified as dithyrambs (originally songs in honour of Dionysus), paeans or hymns. Many fragments which Kenyon was unable to place, and others which have been found since, especially at Oxyrhynchus, have extended the range of information about Bacchylides; and it can now be said that his works included epinicians (at least one book, from which at least 15 poems are known in whole or part), dithyrambs (one book, from which seven poems at least are known), hymns of types other than dithyrambs (known only from quotations and allusions), encomia (after-dinner poems in praise of important people, such as Alexander I, king of Macedon and Hiero I, tyrant of Syracuse) and, as is known from the works of Athenaeus of Naucratis, erotica.

The general consensus of critical opinion about Bacchylides in antiquity is well summed up by the anonymous author of the essay *On Sublimity of Style*, writing probably about the beginning of the Christian era. He seems to divide authors into two main classes: the brilliant writers who are not afraid of facing difficulties, and who often fall heavily in consequence (such as Pindar); and the smooth, equable, rather uninspired writers who never fail because they never attempt anything beyond their capacity (in this second category he puts Bacchylides). So far as the epinicians are concerned, it is possible to test the justice of this comparison between Bacchylides and Pindar, since the third, fourth and fifth of Bacchylides' poems were composed in honour of victories for which Pindar also wrote odes: ode iii is for Hiero I's victory with the four-horse chariot at Olympia in 468, to which, if Sir Maurice Bowra's persuasively argued suggestion is accepted, Pindar's *Pythian ii* also refers; ode iv is for the same victory as *Pythian i* (470); and ode v for the same victory as *Olympian i* (476). By comparison with those of Pindar, Bacchylides' metrical schemes are almost startling in their simplicity and his language usually shows much of the same quality; his treatment of his subjects, and especially his attitude to moral questions, is less austere than Pindar's and it is easy to understand from this why Hiero I seems to have liked Bacchylides more than he did Pindar, and also why the medieval commentators construe Pindar's attack upon his competitors' lack of verbal restraint (*panglôssia*) as a reference to Simonides and Bacchylides. Mostly, Bacchylides' style by its polish and perspicuity merits the praise bestowed on it in antiquity; but it cannot be said that he never fails—at times he shows himself an unscrupulous plagiarist from Pindar, and there are cases which reveal how ill-qualified he really was to challenge Pindar (the scholiasts' suggestion that Pindar's "ape" in *Pythian ii* is an allusion to Bacchylides is seen to be completely justified). For the history of literature, Bacchylides' dithyrambs are more important than his epinicians, since they represent a type of poetry of which we have not as yet any other complete example; among the dithyrambs the most interesting is xviii ("Theseus"), a dialogue in alternate stanzas between a chorus and a single speaker (the relationship of this form to the history of the drama, if any, has not yet been satisfactorily determined).

BACCIO DELLA PORTA: *see* BARTOLOMMEO, FRA.

BACH, the surname of the most consistently successful family in musical history, nearly 40 of its members having established reputations from the late 16th to the early 19th centuries. J. S. Bach is the subject of a separate article; five of his sons are mentioned here. Though falling short of their father's genius, they made varying contributions to the new music of their day.

WILHELM FRIEDEMANN BACH (1710–1784), eldest son of J. S. and Maria Barbara Bach, was born at Weimar, Nov. 22, 1710. His main musical instruction was from his father (who wrote for him, when he was 10, the charming *Klavierbüchlein vor Wilhelm Friedemann Bach* of keyboard pieces). He also studied the violin with J. G. Graun. He matriculated at Leipzig university in 1729. In 1733 he was appointed organist to the Sophienkirche in Dresden. He was already composing successfully and extensively. In 1746 he moved to the Liebfrauenkirche at Halle. At about this time or a little later (perhaps after his father's death in 1750) he evidently began to experience personality difficulties, no doubt latent hitherto. He had been, perhaps, too dependent on his father's help and advice. He has been charged with excessive drinking and other lapses, and, though modern scholars tend to dismiss these charges, they were brought by contemporaries at least one of whom, F. W. Marpurg, might be expected to be reliable. He made a late marriage in 1751. He became restless; applied unsuccessfully for a change of post in 1753 and 1758 and successfully (to the Darmstadt court) in 1762, but did not take up his new appointment; resigned his old post in 1764; and for 20 years sought in vain for regular employment. He must have become almost unemployable through paranoiac touchiness and unreliability; his talents were never doubted, though he imagined that they were. In 1774 he moved to Berlin, where he lived by giving recitals and teaching until his death, July 1, 1784.

His personality problems are discernible in his compositions. The influence of his father's style remained too strong to cast off and too much at variance with the new spirit of the times, and with his own true personality, to use spontaneously and convincingly. He wrote old-fashioned works of little relevance to his day and new-fashioned works too consciously contemporary to be altogether satisfactory, but never found a style that was at the same time true to himself and his age. It is not surprising that his compositions are very few for his many years. Yet their feeling is unmistakable and often impassioned and he had it in him to become a greater composer than his actual achievement makes him.

CARL PHILIPP EMANUEL BACH (1714–1788), second surviving son of J. S. and Maria Barbara Bach, was born at Weimar, March 8, 1714. A precocious musician who remained successful, C. P. E. Bach was his father's true successor and a very important figure in his own generation. In his autobiography he tells us: "For composition and keyboard-playing, I have never had any teacher other than my father." He studied law, taking his degree at Frankfurt in 1735, and, though he probably never had any intention of a career other than music, the legal training gave him an accuracy of mind that helped him become the most outstanding teacher of music of his day. In 1740 he was appointed harpsichordist to Frederick II of Prussia. Frederick was a good flautist and so fond of music that he had his court orchestra accompany him in concertos every night except Mondays and Fridays, which were opera nights. The subservience that he required from his distinguished harpsichordist grew irksome, but it was not until 1767 that C. P. E. Bach was able to resign and to take up an ap-

pointment as *Kapellmeister* at Hamburg. Meanwhile he had married (1744); published (part I, 1753; part II, 1762) his *Versuch über die wahre Art das Klavier zu spielen* (ed. by W. Niemann, 1906; Eng. trans., *Essay on the True Art of Playing Keyboard Instruments* [1949]); and acquired an enviable reputation both as a composer and as a performer on and teacher of the harpsichord and clavichord. He died at Hamburg, Dec. 15, 1788.

Unlike Friedemann, C. P. E. Bach was successful in assimilating the powerful influence of their father and in making the transition into the new style. This represented a break with the past such as very few periods of musical development have equaled. The monumental character of baroque music gave way to a mercurial romanticism for which the favourite contemporary description was "sensibility" (*Empfindsamkeit*). C. P. E. Bach became a leader of this movement but retained the advantage of a solid craftsmanship and assurance for which he always gave full credit to his father's teaching and example.

C. P. E. Bach's compositions are very numerous. Those of his Berlin period are comparatively old-fashioned in the main, because of the conventional preferences of his royal employer. After his move to Hamburg, he developed a more adventurous vein, and his work there did as much as any to open up the future. His influence on Haydn, Mozart and even Beethoven was freely acknowledged, and it is interesting that having influenced Haydn, C. P. E. Bach later allowed himself to be influenced in his turn, just as Haydn allowed himself to be influenced by Mozart.

As a performer, he was famous for the precision of his playing, for the beauty of his touch and for the intensity of his emotion. "He grew so animated and possessed," wrote Charles Burney (*Present State of Music in Germany . . .*, 1773), "that he looked like one inspired. His eyes were fixed, his underlip fell, and drops of effervescence distilled from his countenance."

The influence of C. P. E. Bach's *Essay* was unsurpassed for two generations. Haydn called it "the school of schools." Mozart said, "He is the father, we are the children." Beethoven, when undertaking to teach young Czerny, wrote "be sure of procuring Emanuel Bach's treatise." It is, indeed, one of the essential source books for understanding the style and interpretation of 18th-century music. It had also a particular bearing on the fingering of keyboard instruments, though it was less novel in this respect than has been claimed. It is comprehensive on thorough bass and on ornaments and is an authentic guide to many other refinements of 18th-century performance.

Johann Gottfried Bernhard Bach (1715–1739), third surviving son of J. S. and Maria Barbara Bach, was born at Weimar, May 11, 1715. His father got him the organist's position in the Marienkirche at Mühlhausen in 1735, and in the Jacobikirche at Sangerhausen in 1737. But he was in financial difficulties and in 1738 fled from his creditors; other complaints were also made known against him. His father paid his debts and sought his reinstatement but could not find him. He had hidden in Jena, where he soon died of a fever (May 27, 1739).

Johann Christoph Friedrich Bach (1732–1795), eldest surviving son of J. S. and Anna Magdalena Bach, was born at Leipzig, June 21, 1732. His musical instruction is thought to have been partly in the hands of his father's cousin, Johann Elias Bach. He was made a chamber musician to Count Wilhelm at Bückeburg in 1750, becoming *Konzertmeister* in *c.* 1758. He married Lucia Elizabeth Münchausen, a singer, in 1755. His career was steady and his output of compositions extensive. These are successful rather than important. He had an easier transition into the new style than his older brothers, but perhaps because of this, and because his temperament was easy-going, his work lacked the depth of theirs. It kept well abreast of his times, but without ever leading them. He is at his best in his later symphonies, which reveal the style though not the inspiration of Haydn. He died at Bückeburg, Jan. 26, 1795.

Johann Christian Bach (1735–1782), youngest son of J. S. and Anna Magdalena Bach, called the "English Bach," was born at Leipzig, Sept. 5, 1735. He too is likely to have received his early training from Johann Elias Bach; but after his father's death (1750) he enjoyed the advantage of working with his half-brother, C. P. E. Bach, in Berlin. At the age of 20 he made his way to Italy and in 1756 became a pupil of the famous Padre Martini in Bologna. Having a grace and tactfulness of manner notably lacking in older generations of Bachs, he found a generous patron, while his compositions, though immature, were already well received. They are in a serious style. Having become a Catholic convert, he was appointed organist of Milan cathedral in 1760. His conversion was thought cynical and reprehensible by his strongly Lutheran family, from whom he became somewhat estranged. His taste next turned to opera, and he was thought to have neglected his official duties.

In 1762 he became composer to the King's theatre in London and wrote for it a number of successful Italian operas, besides producing much orchestral, chamber and keyboard music, and a few cantatas. In 1764, he started his fashionable series of concerts with Karl Friedrich Abel (*q.v.*). He received a lucrative appointment as music master to Queen Charlotte and her children and became a social as well as a musical success. In 1772, he was honoured by an invitation to write an opera for the elector at Mannheim. In 1773, he married the Italian singer Cecilia Grassi.

J. C. Bach had no difficult transition to make into the post-baroque style of music; he was born into it. Well-grounded by C. P. E. Bach, thoroughly trained by Martini, naturally receptive to the latest Italian music in Milan, Naples and elsewhere, he early became a fashionable composer. Among those who learned from and greatly respected him was the young Mozart. Nevertheless, his early success apparently relieved him of any urgent pressure to continue developing, and though always a sensitive and imaginative composer, he never grew to be a profound one. Running into financial and other difficulties, he seemed unable to respond to the challenge, and died, in London, Jan. 1, 1782.

See Karl and I. S. Geiringer, *The Bach Family* (1954), for an excellent bibliography concerning the Bach family and their compositions.
(R. Do.)

BACH, (JULIUS) CARL VON (1847–1931), German specialist in mechanics of materials, was born in Stollberg, Saxony, March 8, 1847, the son of a saddler and wainwright. He first learned the machinist's trade. In 1866 he entered the Polytechnikum at Dresden. After service in the artillery in the Franco-Prussian War, he entered the technical school at Karlsruhe, from which he graduated in 1873. After industrial experience in Vienna and Bautzen, he was appointed in 1878 professor of mechanical engineering at the technical school at Stuttgart, where he remained until retirement in 1922. His work in the testing of materials led to the establishment of a great engineering laboratory at Stuttgart in 1900.

Bach was a pioneer in the determination of suitable stresses to be used in the design of machine elements. His *Elastizität und Festigkeit* went through nine editions between 1881 and 1924 and exerted far-reaching influence. His work also gave direction to the design procedures for concrete and reinforced concrete structures.

He died in Stuttgart on Oct. 10, 1931. (S. C. Hr.)

BACH, JOHANN SEBASTIAN (1685–1750), German composer, the most important member of a remarkable family of musicians and the chief representative of the German late baroque period. His contemporaries admired him as an outstanding harpsichordist, organist and expert on organ-building, but found many of his compositions old-fashioned. Posterity has done him more justice, and he is generally regarded as one of the greatest composers of all time.

The Bachs (*q.v.*) were proud of their achievements, and about 1735 Sebastian drafted a genealogy, *Ursprung der musicalisch-Bachischen Familie*. He traced his ancestry back to his great-great-grandfather Veit Bach, a Lutheran baker (or miller), who was driven from Hungary to Wechmar in Thuringia by religious persecution late in the 16th century and died in 1619. There were Bachs in the area before this, and it may be that when Veit moved to Wechmar he was returning to his birthplace. He used to take his cittern to the mill and play it while grinding was going

on. Sebastian remarked, "A pretty noise they must have made together! However, he learnt to keep time, and this apparently was the beginning of music in our family."

Until the birth of Sebastian, his was the least distinguished branch of the family; its members had been competent practical musicians, but not composers such as Johann Christoph (1642–1703), Johann Michael (1648–94) and Johann Ludwig (1677–1743). In later days the most important musicians in the family were Sebastian's sons, Wilhelm Friedemann (1710–84), Carl Philipp Emanuel (1714–88), and Johann Christian (the "English Bach," 1735–82) (*see* BACH). Emanuel's compositions influenced Haydn and Mozart; his book on keyboard-instrument playing, *Versuch über die wahre Art das Klavier zu spielen* (1753–62), remained in use until Beethoven's time and is more valuable than ever today. But the family talent was not exclusively musical; some of the 18th-century Bachs were competent painters.

LIFE

Early Years.—J. S. Bach was born at Eisenach, Thuringia, on March 21, 1685, the youngest child of Johann Ambrosius Bach (1645–95) and Elisabeth Lämmerhirt (1644–94). Ambrosius was a string player, employed by the town council and perhaps by the ducal court of Eisenach. In spite of his complaints of poverty he must have been reasonably well off, to judge by the social status of his two wives.

Sebastian started school in 1692 or 1693 and did well in spite of frequent absences. Of his musical education at this time nothing definite is known; but he may have picked up the rudiments of string playing from his father, and no doubt he attended St. George's church, where Johann Christoph Bach was organist until 1703.

By 1695 both his parents were dead, and he was taken in by his eldest brother, also named Johann Christoph (1671–1721), organist at Ohrdruf. This Christoph had been a pupil of Johann Pachelbel; he apparently gave Sebastian his first formal keyboard lessons. The latter again did well at school, until in 1700 his voice secured him a place in a select choir of poor boys at the school of St. Michael's church, Lüneburg.

His voice must have broken soon after this; but he remained at Lüneburg for a time, making himself generally useful. No doubt he studied in the school library, which had a large and up-to-date collection of church music; no doubt also he heard Georg Böhm, organist of St. George's church; and certainly he visited Hamburg to hear J. A. Reinken at St. Catherine's and contrived to hear the French orchestra maintained by the duke of Celle.

He seems to have returned to Thuringia in the late summer of 1702, for at some time between July and November he applied for the post of organist at Sangerhausen. But for ducal interference he would have obtained it; and when every allowance is made for the low technical standards of that area, this means that he must already have been a reasonably proficient organist. His experience at Lüneburg, if not at Ohrdruf, had turned him away from the secular string playing tradition of his immediate ancestors; thenceforth he was, chiefly though not exclusively, a composer and performer of keyboard and sacred music.

The next few months are wrapped in mystery; but by March 4, 1703, he was a member of the orchestra employed by Duke Johann Ernst of Weimar (brother of Duke Wilhelm Ernst, whose service Bach entered in 1708). This post was a mere stopgap; he probably already had his eye on the organ then being built at St. Boniface, Arnstadt. When it was finished he helped to test it, and in Aug. 1703 he was appointed organist—all this at the age of 18. Arnstadt documents imply that he had been court organist at Weimar; this is incredible, though it is likely enough that he had occasionally played there.

Arnstadt.—At Arnstadt Bach devoted himself to keyboard music, the organ in particular. While at Lüneburg he had apparently had no opportunity of becoming directly acquainted with the playing and compositions of Dietrich Buxtehude (*q.v.*); in Oct. 1705 he repaired this gap in his knowledge by obtaining a month's leave and walking to Lübeck (over 200 mi.). His visit must have been profitable, for he did not return until about the middle of Jan. 1706. In February his employers complained about his absence and other things as well: he had harmonized the chorales so freely that the congregation could not sing to his accompaniment, and, above all, he had not produced any cantatas. Strictly speaking, he was not bound to do so, for he was employed purely as an organist; but no doubt the real reasons for his neglect were that he was temporarily obsessed with the organ and was on bad terms with the local singers and instrumentalists, who were not under his control and did not come up to his standards. In the summer of 1705 he had made some offensive remark about a bassoon player, which led to an unseemly scuffle in the street.

His replies to these complaints were neither satisfactory nor even accommodating; and the fact that he was not dismissed out-of-hand shows that his employers were as well aware of his exceptional ability as he was himself and were reluctant to lose him.

Mühlhausen.—In 1707 he obtained a better post at St. Blasius, Mühlhausen. He moved there in September and married his cousin Maria Barbara Bach (1684–1720) at Dornheim on Oct. 17. At Mühlhausen things seem, for a time, to have gone more smoothly. He produced two or three cantatas, including no. 71 (Feb. 4, 1708), which was printed at the expense of the city council; copied music, to enlarge the choir library; tried to encourage music in the surrounding villages; and was in sufficient favour to be able to interest his employers in a scheme for rebuilding the organ (Feb. 1708). His real reason for resigning on June 25, 1708, is not known. He himself said that his plans for "regular [concerted] church music" had been opposed by members of his own congregation and that his salary was inadequate. It is generally supposed that he had become involved in a theological controversy between his own Pastor Frohne and Archdeacon Eilmar of St. Mary's. Certainly he was friendly with Eilmar, who provided him with librettos and became godfather to Bach's first child; and it is likely enough that he was not in sympathy with Frohne, who, as a Pietist, would have frowned on elaborate church music. At all events, his resignation was accepted, and he moved to Weimar shortly afterward; but he continued to be on good terms with Mühlhausen personalities, for he supervised the rebuilding of the organ, is supposed to have reopened it on Oct. 31, 1709, and composed a cantata for Feb. 4, 1709, which was printed, but has completely disappeared.

Weimar.—It has now been established that Bach from the outset was court organist at Weimar as well as a member of the orchestra. Encouraged by Duke Wilhelm Ernst, he once more concentrated on the organ. Late in 1713 Bach had the opportunity of succeeding F. W. Zachau at St. Mary's church, Halle; but the duke raised his salary, and he stayed on at Weimar, becoming *Konzertmeister* on March 2, 1714, with the duty of composing a cantata every month. He became friendly with his relation Johann Gottfried Walther, the lexicographer (1684–1748), who was organist of the town church, and, like Walther, he took part in the musical activities at the Gelbes Schloss, then occupied by Duke Wilhelm's two nephews, Ernst August and Johann Ernst. He taught them both. The latter was a talented composer, who wrote concertos in the Vivaldi manner, some of which Bach arranged for keyboard instruments; the boy died in 1715, in his 19th year. During these years Bach occasionally visited Weissenfels, in March 1714 to serve as a godfather, in Feb. 1716 to take part in a court celebration that included a performance of his first secular cantata, no. 208.

J. S. Drese, the Weimar *Kapellmeister*, died on Dec. 1, 1716, and was succeeded by his nonentity of a son. Bach presumably resented being thus passed over; and in due course he accepted an appointment as *Kapellmeister* to Prince Leopold of Köthen, which was confirmed on Aug. 5, 1717. Duke Wilhelm, however, refused to accept his resignation—partly, perhaps, because of Bach's friendship with the duke's nephews, with whom the duke was on the worst of terms. About September, a contest between Bach and the famous French organist Louis Marchand was arranged at Dresden. The exact circumstances are not known;

but Marchand avoided the contest by leaving Dresden a few hours before it should have taken place. By implication, Bach won. Perhaps this emboldened him to renew his request for permission to leave Weimar; at all events he did so, but in such terms that the duke imprisoned him for a month. Released on Dec. 2, he moved to Köthen a few days later.

Köthen.—There, as *Kapellmeister*, he was concerned chiefly with chamber and orchestral music. Even though some of the works may have been composed earlier and revised later, it was at Köthen that the sonatas for violin and clavier, viola da gamba and clavier, and the works for unaccompanied violin and cello were put into something like their present form. The *Brandenburg Concertos* were finished by March 24, 1721; in no. 6—so it has been suggested—Bach bore in mind the technical limitations of the prince, who played the gamba. Bach played the viola for choice; he liked to be "in the middle of the harmony." He wrote a few cantatas, for the prince's birthday and other such occasions; most of these seem to have survived only in later versions, adapted to more generally useful words. He also found time to compile educational keyboard works: the *Clavierbüchlein* for W. F. Bach (begun Jan. 22, 1720); some of the French suites; the first book (1722) of *Das wohltemperierte Klavier* (*The Well-Tempered Clavier*, consisting of two books, each of 24 preludes and fugues in all keys and known as the "Forty-eight"); and the Inventions (1723). In the last two collections he made use, to some extent, of material that had already appeared in the *Clavierbüchlein*, and some of the "Forty-eight" probably go back a good deal further.

Maria Barbara Bach died unexpectedly and was buried on July 4, 1720. About November, Bach visited Hamburg; his wife's death may have unsettled him and led him to inquire after a vacant post at St. James's church. Nothing came of this; but he played at St. Catherine's in the presence of J. A. Reinken (1623–1722). After hearing Bach improvise variations on a chorale, the old man said, "I thought this art was dead; but I see it still lives in you."

On Dec. 3, 1721, Bach married Anna Magdalena Wilcken (1701–60), daughter of a trumpeter at Weissenfels. The courts of Weissenfels and Köthen were on friendly terms, and Anna, who was a soprano, had visited Köthen on various occasions and apparently had been employed there since the autumn of 1720.

Apart from his first wife's death, these four years at Köthen were probably the happiest of Bach's life. He was on the best of terms with the prince, who was genuinely musical; and in 1730 Bach said that he had expected to end his days there. But the prince married on Dec. 11, 1721, and conditions deteriorated. The princess—described by Bach as "an *amusa*" (*i.e.*, opposed to the muses)—required so much of her husband's attention that Bach began to feel neglected. He also had to think of the education of his elder sons, born in 1710 and 1714; and he probably began to think of moving to Leipzig as soon as the cantorate fell vacant with the death of Johann Kuhnau on June 5, 1722, even though, as he said, he did not like the idea of becoming "a mere cantor" after having been a *Kapellmeister*. His friend G. P. Telemann (*q.v.*) applied and was appointed but withdrew in November. Bach applied in December, but the post was offered to Christoph Graupner, *Kapellmeister* at Darmstadt. As the latter was not sure that he would be able to accept, Bach gave a trial performance (Cantata 22) on Feb. 7, 1723; and when Graupner withdrew (April 9), Bach was so deeply committed to Leipzig that, although the princess had died on April 4, he applied for permission to leave Köthen. This he obtained on April 13, and on May 13 he was sworn in at Leipzig.

He was appointed honorary *Kapellmeister* to Köthen, and both he and Anna were employed there from time to time until the prince died, on Nov. 19, 1728. Memorial services were held in March 1729; on March 24 Bach conducted a funeral ode, consisting partly of adaptations from the *Passion According to St. Matthew*. Anna and Friedemann Bach were among the performers.

Leipzig.—As cantor of St. Thomas' school, Bach had to supply performers for four churches. At St. Peter's, the choir merely led the hymns. At the New church, St. Nicholas' and St. Thomas', part-singing was required; but Bach himself conducted only at the last two. He also had various nonmusical duties connected with the school.

Since Bach regarded the cantorate as a step downward in the social scale and had a fully justified sense of his own importance as the greatest organist in Germany, whereas his employers regarded him as a rather poor substitute for Telemann and Graupner, friction was inevitable. Bach frequently absented himself without leave, playing or examining organs, taking Friedemann to hear the "pretty tunes" at the Dresden opera and fulfilling the duties of the honorary court posts that he contrived to hold all his life. To some extent, no doubt, he accepted engagements because he needed money; he complained in 1730 that his income was less than he had been led to expect (there were not enough funerals); but obviously his routine work must have suffered. On the other hand, the authorities insisted on admitting unmusical boys to the school, thus making it difficult for Bach to keep his churches supplied with singers; furthermore, they refused to spend enough money to keep a decent orchestra together. The resulting ill feeling had become serious by 1730. It was temporarily dispelled by the tact of a new rector, J. M. Gesner, who admired Bach and had known him at Weimar; but Gesner stayed only until 1734 and was succeeded by J. A. Ernesti, a young man with up-to-date ideas on education, one of which was that music was not one of the humanities but a time-wasting side line. Trouble did not actually begin until July 1736; it then took the form of a dispute over Bach's right to appoint prefects and became a public scandal. Fortunately for Bach, he became court composer to the elector of Saxony in Nov. 1736. As such, after some delay, he was able to induce his friends at court to hold an official inquiry, and his dispute with Ernesti was settled in 1738. The exact terms of the settlement are not known; but thereafter Bach did as he liked.

From what has been said, it will be understood that after his first two or three years at Leipzig—during which he produced a large number of new cantatas, sometimes at the rate of one a week—Bach lost interest in composing church music. In 1726 he began to publish the clavier *Partitas* singly, with a collected edition in 1731; according to J. N. Forkel (*see* below), their difficulty attracted attention. The second part of the *Clavierübung* followed in 1735, the third in 1739; both were reprinted. From *c.* 1729–36 Bach was honorary *Kapellmeister* to Weissenfels; and from 1729 to 1737, and again from 1739 for a year or two, he directed the Leipzig *Collegium Musicum*, for whose concerts some of his concertos are supposed to have been adapted. About 1733 he began to produce cantatas in honour of the elector of Saxony and his family, evidently with a view to the court appointment that he secured in 1736; many of these secular movements were adapted to sacred words and reused in the *Christmas Oratorio* (performed 1734–35). The Kyrie and Gloria of the B minor Mass, written in 1733, were also dedicated to the elector; the rest of the Mass was put together during Bach's last years. On his visits to Dresden he had won the regard of Count Hermann Karl von Keyserlingk, the Russian envoy, who commissioned the so-called *Goldberg Variations*; these were published about 1742, and Book II of the "Forty-eight" seems to have been completed about the same time. For the rest, he wrote a few cantatas, revised some of his Weimar organ works and published the so-called *Schübler Chorale Preludes* about 1746. In May 1747 he visited his son Emanuel at Potsdam and played before Frederick II (the Great) of Prussia; in July his improvisations, on a theme proposed by the king, took shape as *Das musikalische Opfer* (*The Musical Offering*). In June 1747 he joined a Society for the Promotion of Musical Science that had been founded in 1738 by his former pupil L. C. Mizler; he presented the canonic variations on *Vom Himmel hoch da komm' ich her* to the society, in manuscript, and afterward published them.

It is generally supposed that Bach was a devout orthodox Lutheran. He may have had some leanings toward Pietistic emotionalism; but, as a professional musician, he cannot have been fully in sympathy with that revivalistic movement, which dis-

approved of elaborate music. He appears to have been a good husband and father. There is amusing evidence of a certain thriftiness, a necessary virtue, for he was never more than moderately well off, and he delighted in hospitality. Living as he did at a time when music was beginning to be regarded as no occupation for a gentleman, he occasionally had to stand up for his rights both as a man and as a musician; he was then obstinate in the extreme. But no sympathetic employer had any trouble with Bach, and with his professional brethren he was modest and friendly. He was also a good teacher and from his Mühlhausen days onward was never without pupils.

Of Bach's last illness little is known, except that it lasted several months and prevented him from finishing *Die Kunst der Fuge* (*The Art of Fugue*). His constitution was undermined by two unsuccessful eye operations performed by the chevalier John Taylor, the itinerant English quack who numbered Handel among his other failures; and he died on July 28, 1750. His employers proceeded with relief to appoint a successor; Burgomaster Stieglitz remarked, "The School needs a cantor, not a *Kapellmeister*—though certainly he ought to understand music." Anna Magdalena was left badly off. For some reason her stepsons did nothing to help her, and her own sons were too young to do so. She died on Feb. 27, 1760, and was given a pauper's funeral.

Unfinished as it was, *The Art of Fugue* was published in 1751. It attracted little attention and was reissued in 1752 with a laudatory preface by F. W. Marpurg, the well-known Berlin theorist, who later became director of the royal lottery. In spite of Marpurg, and of some appreciative remarks by Johann Mattheson, the Hamburg critic, only about 30 copies had been sold by 1756, when Emanuel Bach offered the plates for sale. As far as is known they were sold for scrap.

Emanuel Bach and J. F. Agricola (a pupil of Sebastian's) wrote an obituary; Mizler added a few closing words and published the result in the journal of his society (1754). This was reprinted in *Bach-Jahrbuch*, 1920, and there is an English translation in *The Bach Reader* (*see* below). Though incomplete and inaccurate, the obituary is of very great importance as a firsthand source of information.

MUSIC

The Revival.—For about 50 years after Bach's death, his music was neglected. This was only natural. The same fate befalls many authors and composers, even in this historically minded age; and the musical world of 1750 was not historically minded. Besides a fashionable desire for novelties, there was a sincere though mistaken belief that music was getting better and better every year; in the days of Haydn and Mozart, no one could be expected to take much interest in a composer who had been considered old-fashioned even in his lifetime—especially as his music was not readily available, and half of it (the church cantatas) was fast becoming useless, as a result of changes in religious thought.

At the same time, musicians of the late 18th century were neither so ignorant of Bach's music nor so insensitive to its influence as some modern authors have suggested. Manuscripts of that date are much more numerous than one would suppose from the inadequate lists given in 19th-century publications; and such important works as the clavier *Partitas*, the *Concerto in the Italian Style in F major* (*Italian Concerto*) and the *Goldberg Variations* circulated in editions of perhaps 100 or 200 copies. Furthermore, historians have a natural tendency to concentrate on the men from whom a great composer learned, rather than on the men who learned from him. Thus, much more is known about the Buxtehudian elements in Sebastian Bach than about the Sebastianic elements in Emanuel Bach, and probably both Emanuel's debt to his father and the latter's indirect influence on the Viennese classics are underrated. In any case, if Bach influenced only a few people directly, he did at least influence the three who mattered: Haydn, Mozart and Beethoven.

A. F. C. Kollmann, a Hanoverian settled in England, was one of the first to see that Bach's music was worth reviving. He planned to publish the "Forty-eight Preludes and Fugues," but failed to obtain the necessary support and was anticipated by Nägeli and Simrock in 1801. J. N. Forkel published a *Life and Works* in 1802, and acted as adviser to Hoffmeister and Kühnel, whose collected edition, begun in 1801, was cut short by the activities of Napoleon. With these events the revival began in earnest. Four volumes of chorale preludes were issued by Breitkopf and Härtel in 1803–06: the Six "Great" Preludes and Fugues (for organ) by Riedl of Vienna, about 1812; and the latter must have been in demand, for Riedl's successors kept them in print until 1838 at least. In England, Kollmann published the *Chromatic Fantasy and Fugue in D minor* in 1806, and a translation of Forkel in 1820; Samuel Wesley and C. F. Horn began to publish the organ sonatas in 1809, and the "Forty-eight" in 1810.

By 1829 a representative selection of the keyboard music was available; but very few of the vocal works were published, most of them being considered unsuitable for performance in church. In that year Eduard Devrient and Mendelssohn took the next step with their centenary performance of the *St. Matthew Passion*. It and the *Passion According to St. John* were both published in 1830; the B minor Mass followed, half in Nov. 1832, the rest in 1845. Peters began a collected edition of "piano" and instrumental works in 1837; the organ works followed in 1844–52; and Mendelssohn edited an important collection of chorale preludes for Coventry and Hollier in 1845.

Encouraged by Schumann, the Bachgesellschaft (BG) was founded in the centenary year 1850. By 1900 all the known works had been published, and the BG was succeeded by the Neue Bachgesellschaft (NBG). It organizes festivals and publishes popular editions, but is chiefly important for its research journal, the *Bach-Jahrbuch* (from 1904).

By 1950 the deficiencies of the BG edition had become painfully obvious, and the Bach-Institut was founded, with headquarters at Göttingen and Leipzig, to produce a new standard edition (the *Neue Bach-Ausgabe* or NBA), expected to comprise 84 volumes.

Besides these musical publications, biographical and critical works appeared. The most important was P. Spitta's monumental study, *Johann Sebastian Bach*, 2 vol. (1873, 1880), covering not only Bach's life and works but also a good deal of the historical background. Although wrong in many details, the book is indispensable to the Bach student. Valuable work, though more limited in scope, was done by C. H. Bitter, André Pirro, Albert Schweitzer, C. H. H. Parry, Harvey Grace and C. S. Terry, among others.

There had been a certain amount of antiquarian activity before 1800, at any rate in England; but the Bach revival was the first conspicuous example of the deliberate exhumation of old music, accompanied by biographical and critical studies; and it served as an inspiration and a model for subsequent work of that kind. The fact that library shelves groan under the weight of collected editions is largely the result of the enthusiasm of A. F. C. Kollmann, J. N. Forkel and Samuel Wesley, and the critical insight of P. Spitta. The revival is thus an interesting subject in its own right, and F. Blume's account of it, *Two Centuries of Bach* (1950), is well worth reading.

The Music in General.—Bach's working life, from about 1700 to 1750, covered a period of transition in musical history. The antique idea that the arts make their effect by "imitating nature" and appealing to the expert intellect fell out of favour, as being an incomplete explanation, and was largely replaced by the notion (perhaps equally unsatisfactory) that art ought to appeal to the emotions of the layman—the emotion felt by the composer being relived by the performer and so communicated to the listener—and that music could be explained in terms of rhetoric. These ideas—to the effect that the function of art is not to teach but to arouse feeling—were nothing new. In religious art they can be traced back to the Council of Trent (1545–63); and with them went an increasing emphasis on the personality of the creative artist, which can be traced back to about the same date. Ever since G. Vasari's *Vite* (1550) there had been an uneasy feeling that a painter's sketch might in some ways be better than his finished picture, because expressed with less restraint and more closely related to his original inspiration. These aesthetic principles led to a temporary rejection of counterpoint (*q.v.*) in

favour of homophonic tunefulness and clear-cut sectional forms, and in due course produced the classical sonata; they also affected the musical practice of symbolism.

Texture.—Soon after 1700 Telemann, like other bright young devotees of the Leipzig opera, was preaching the virtues of what he called "the new school of melodic composition" as against "the unmelodious artifices of the ancients." He meant that intricate counterpoint and esoteric symbolism are no substitutes for a good tune. Between 1700 and 1708 Bach lived either in the far north or in the backwoods of Thuringia, and the ideas of the new school had little effect on him till he moved to Weimar, became friendly with Telemann and saw how those ideas had already been put into practice by Italian concerto-composers such as Vivaldi. Between 1708 and 1714 his style underwent a profound change; and thereafter, although he never went all the way with the innovators, he was never an old fogy who deliberately turned his back on the new music of his day. Albert Schweitzer's fatally memorable dictum ("Bach is thus a terminal point. Nothing comes from him; everything merely leads up to him") is a dangerously misleading half-truth. It has done incalculable harm, by leading students to suppose that Bach's aesthetic principles were those of 1600 rather than of 1710, and that in such practical matters as interpreting ornaments the testimony of Bach's own son is less valuable than that of any foreigner or German nonentity who was born a few years before 1685.

Of Bach's major works, the first that became readily accessible was the "Forty-eight Preludes and Fugues." As a desiccated form of fugue makes a convenient subject for examinations, the emphasis has always been on the fugues, with the result that Bach's name has become almost synonymous with fugue and with elaborate counterpoint in general. In fact, he wrote much less counterpoint than he is usually given credit for; if circumstances had permitted the cantatas and the clavier *Partitas* to become household words, a very different conception of Bach would have come into being. *Secco* recitatives are not contrapuntal; arias accompanied by *continuo* alone are not necessarily any more contrapuntal than 19th-century songs accompanied by arpeggios or repeated chords; arias for *continuo* and one *obbligato* instrument are comparable with songs whose accompaniment has some independent interest: and such movements bulk large in Bach's output. From this point of view the dance pieces also are worth examining; many of them can only be described as accompanied melodies.

Bach's attitude was shrewdly summed up by an anonymous author (probably Mizler) in 1738: "if Herr Bach often writes more elaborate inner parts than other composers do, he has modelled his music on that of 20 or 25 years ago. He can write otherwise, however, when he wants to." The author goes on to say that a recent secular cantata, whose music has been lost, was "entirely according to the latest taste, and approved by everyone." These remarks were provoked by J. A. Scheibe's attack on Bach's "turgidity," in 1737. At the time, Scheibe's criticism was not unreasonable, as can be seen from Mizler's admission about Bach's unfashionably elaborate inner parts. But it is a mistake to ignore Mizler's words: "He can write otherwise, however, when he wants to," or to forget that Scheibe himself had realized this by 1739, when he praised the *Italian Concerto* to the skies.

Again, much has been made of the story that Bach used to take Friedemann to Dresden "to hear the pretty tunes." It is generally assumed that "pretty tunes" was an expression of contempt. The fact remains that Bach frequently visited Dresden, and that in his last years (according to Emanuel) he admired, among others, Telemann, J. A. Hasse and both the Grauns (J. G. and C. H.). Emanuel wrote this in 1775. Hasse had retired, Telemann and the Grauns were dead; and there seems no reason why he should have misrepresented his father's taste.

So far, the safest conclusion seems to be that Bach was not a bigoted reactionary but a moderate progressive; and there is other evidence pointing in the same direction.

Forms.—In discussing Bach's forms, one must distinguish between those that are intrinsically logical and those that are not, a reasonable key-scheme always being assumed. Intrinsically logical forms—fugues, ground basses, ritornello and *da capo* movements—are all based, like the classical sonata, on repetition of recognizable themes. Illogical forms may be exemplified by such things as the *Chromatic Fantasia*—rhapsodical outpourings, beyond the reach of structural analysis, but effective when based on a rhetorical scheme of contrast or intensification—and also by chorale preludes of the motet type. Here each line of the chorale is fugued separately; and since, as a rule, most of the lines are different, such a prelude is simply a string of short fugues on unrelated subjects. It requires educated listeners who know the chorale by heart; and such coherence as it may have is in fact supplied by the listeners, who note each line of the chorale as it occurs and consciously look forward to the next one.

As one would expect, 18th-century developments in matters of form can be interpreted as rational consequences of the increasing emphasis on emotion, rather than intellectual activity, as the source of artistic enjoyment. Rhapsodical writing could be regarded as written-out improvisation—a close approximation to direct emotional contact between composer and listener, having virtues similar to those of a painter's sketch. It became less common but did not disappear. Motet form, because of its intrinsic incoherence, and the ground bass, because of its very narrow limitations, became less popular. Fugue, as such, suffered for its supposed turgidity; but it staged a comeback, even in advanced circles in Berlin, about 1750, and some elements of fugue technique remained in favour throughout the period. They were too useful to be discarded; a fugal exposition, which could be written to rule in a few minutes, was a good way of getting a movement started and called for little real thought. But the typical forms of the period were the intrinsically logical ones that depended on repetition but were not necessarily contrapuntal—the ritornello and *da capo* forms, leading ultimately to the classical sonata.

Here again Bach appears as a moderate progressive. At Weimar, between 1708 and 1714, he studied the concertos of such composers as Vivaldi, and thereafter his taste in form was that of his age. He almost ceased to write rhapsodically. He did not reject motet form—the prelude on *Vor deinen Thron*, supposed to have been dictated on his deathbed, is not only in motet form but, what is much more significant, was deliberately rewritten in that form—but he used it less frequently. He continued to use fugal devices and to write whole fugues, but until his last years (when counterpoint was again just beginning to be considered respectable) he showed no special liking for the form. His favourite forms were the intrinsically logical but noncontrapuntal ones. The *da capo* and ritornello principles governed a host of arias and concerto movements, influenced many of his larger fugues (especially the mature ones for organ) and profoundly affected his treatment of chorales. A mature setting of a chorale melody, whether in an organ prelude or a cantata chorus, is usually a ritornello movement, constructed on concerto principles. The chorale lines are interludes, comparable with the solo sections of a concerto; what holds the movement together is the repetition of ritornello material—material that often has nothing to do with the chorale.

Occasionally Bach looked further into the future. As is well known, some of the preludes of the "Forty-eight" come very close to sonata form; and there are other examples in the clavier *Partitas*. The *sarabande* of *Partita IV* has a "first subject," a "second subject" in the dominant, a long modulating "development" and a "recapitulation" of first and second subjects, both in the tonic. The *corrente* of *Partita VI* has a similar but much larger scheme, and these are merely two examples out of several in these neglected works, written about 1725–30. In other ways also, the *Partitas* show the supposedly reactionary Bach demolishing conventions. The saraband had become stereotyped as a sober little piece in triple time, almost always beginning on the first beat of the bar. In the last four *Partitas*, three sarabands begin emphatically on an offbeat, and all four are not only totally unlike the stereotype but also totally unlike each other. The term saraband is here nothing more than a conventional title for a fancy piece in triple time. When Emanuel Bach wrote a fancy saraband and called it *La Stahl* (about 1762), he was doing little more than his father had done in 1725.

It must also be remembered that Bach was one of the first composers to write harpsichord concertos, and to use the harpsichordist's right hand as an *obbligato* part in trio sonatas. As for his organ solos in the trio-sonata style, they may perhaps be a synthesis of ideas derived from certain chorale-prelude types, from chamber music and from the Italianate concertos that he and Johann Gottfried Walther arranged for organ; but the synthesis was an entirely original one. Bach seems at first to have written these trios singly; he then used them in two ways. While at Weimar he experimented two or three times with a sonatalike (or rather, concertolike) organ form obtained by inserting a trio between a prelude and a fugue. At least one of these experiments (with the short Prelude and Fugue in C [*Bach-Werke-Verzeichnis,* BWV 545]) was successful; and the only reason why it is not familiar today is that Bach himself withdrew the central trio and used it in a complete organ sonata. The date at which Bach began to think in terms of complete sonatas is not known, perhaps at Weimar, certainly before 1731, and the complete sonatas were even more unprecedented than the single trios. The idea was taken up by his pupils, and in 1788 Emanuel Bach described the sonatas as "so galant that they still sound very well." In all these ways, therefore, Bach showed an inventiveness that was entirely in accordance with the spirit of the age.

Symbolism.—The question of Bach's attitude to symbolism is bound up with that of his "modernity." The symbolism that has been read into his music is, roughly speaking, of two kinds: abstract and pictorial. Schweitzer and his followers thought that Bach used a system of motives, not unlike Wagner's, with certain rhythmic and melodic figures standing for such abstractions as joy or confident faith. It is easy to show that Bach did not use these motives consistently, and that they are nothing more than stock figures. Again, various theorists of Bach's day made lists of keys that they considered suitable for joyful or sorrowful music. The lists do not agree, and during Bach's lifetime the whole idea became discredited; it had been challenged by Johann Kuhnau, in the preface to his *Bible Sonatas,* as early as 1700. Today there can be few who believe that Bach made any serious use of abstract symbolism.

Pictorial symbolism occurs when a composer writes a rising scale to match words that speak of rising from the dead; or a descending chromatic scale (depicting a howl of pain), to sorrowful words; or a fugue with ten entries of the subject, to words that refer to the Ten Commandments. It occurs only in connection with words—in vocal music, and in chorale preludes, where the words of the chorale are in the listener's mind. There is no point in looking for resurrection motives in the "Forty-eight." But, even so, pictorialism is common in Bach. The question is: Why did he use it? Did he expect his audiences to listen for it and understand it, and did he think that it intensified the expressive power of his music? As he is not known to have said a word about this or any other form of symbolism, the answer to this question is a matter of opinion.

Pictorialism seems to be a fundamental musical instinct; it has been used by almost every composer of importance from the madrigalists to the present day. In 1597 Thomas Morley taught it as a matter of course, a way of "imitating Nature," and it was common throughout the 17th century; but about 1700 it began to be regarded with suspicion, as men came to realize that a composer's business is to grasp the emotional drift of his libretto as a whole and that pictorial emphasis on individual words often injures the general effect. Furthermore, the forms then coming into use required the same notes to be repeated to different words, and this made pictorialism difficult, if not impossible. The result was that after 1750 composers and commentators either said nothing about pictorialism or apologized for it (as Beethoven did in the *Pastoral Symphony*)—until Schweitzer thought he could trace another quasi-Wagnerian system of "motives" in Bach's pictorialism.

Believing, as he did, that Bach drew his inspiration exclusively from the past, Schweitzer inevitably supposed that he took pictorialism seriously as a means of expression. Now that Bach is beginning to be regarded as a moderate progressive, one has to ask whether he really agreed with Morley and "the ancients," rather than with the skeptical Kuhnau (1700) and such members of the new school as J. D. Heinichen (1683–1729).

By 1711, Heinichen regarded pictorialism less as a means of expression than as an aid to invention. In those days composers earned their living by composing and often had to set dull words in a hurry. Heinichen pointed out that if a poem, as a whole, suggested nothing to a composer, he should look for individual words that could be treated pictorially. A dull poem about love might nevertheless suggest "the fires of love" and thus a flickering "fire motive." Alternatively, the composer might visualize a pompous man making advances to his lady and write a "comic" bass theme depicting his strutting gait and frequent bows. It is worth noting that Heinichen's "comic" theme incorporates a descending chromatic scale. This shows that orthodox commentators are wrong in imagining that such scales were universally understood as "grief motives."

There are three strong objections to the post-Schweitzerian view that Bach regarded pictorialism as a means of expression. Firstly, his pictorialism is sometimes inappropriate; as in the last aria of Cantata 166, where a solemn warning against earthly joys—"When Fortune laughs upon you, beware!"—is set to a laughter motive. Secondly, in revising a movement he sometimes destroyed its pictorial features; as in the *Deposuit* aria of the *Magnificat,* at the end of the ritornello. The first version puts the mighty down from their seat; the second version, musically superior, puts them most emphatically up. Thirdly, he adapted pictorial movements to other words, as in many of the pieces that were borrowed for use in the *Christmas Oratorio.* The allusion to writhing serpents in the secular Cantata 213 (no. 9, middle section) reappears in no. 4 of the *Oratorio* "Bereite dich, Zion" as a harmless arpeggio accompaniment.

On the whole, it is reasonable to conclude that with Bach, as with Heinichen in 1711 and Mattheson in 1739, pictorialism was often nothing more than an aid to invention. Schweitzer himself remarked on the excessive symbolism of the chorale cantatas; significantly, it is now known that these works were written under pressure—52 of them in one ecclesiastical year. Furthermore, Bach's best works are often not conspicuously pictorial. When a commentator spills much ink over a "masterpiece of symbolism," one often finds dull or unsuitable music, set to dull words.

Number symbolism is sometimes pictorial; in the *St. Matthew Passion* it is reasonable that the question "Lord, is it I?" should be asked 11 times, once by each of the faithful disciples. But almost any number may be called "symbolic" (3, 6, 7, 10, 11, 12, 14 and 41 are only a few examples); any multiple of such a number is itself symbolic; and the number of sharps in a key signature, notes in a fugue subject, entries of the subject, bars, notes in a whole movement, a chosen section of a movement or a single part may all be considered significant. As a result, it is easy to find symbolic numbers anywhere and ridiculous to suppose that such discoveries have any meaning.

To sum up: It is permissible to suppose that Bach was as up-to-date as Heinichen. If so, he used pictorialism partly by instinct, like any other composer; partly by habit, because he was used to seeing sorrowful words set to chromatic scales; and partly as an aid to invention. The reason why the subject has had to be discussed at some length is that it is greatly overemphasized in many otherwise excellent writings on Bach. It is in fact unimportant. It helps one to understand how he came to write such pointless movements as the last aria of Cantata 166; otherwise, it needs attention only when it is obvious; and in such cases Bach's pictorialism can be taken for granted, like Byrd's, Purcell's, Beethoven's or Wagner's. It is not necessary to read books about it.

Stylistic Development.—Any discussion of this subject must be tentative. Many of what seem to be Bach's earliest works are undated and probably undatable. Moreover, Spitta's chronology, which remained almost unchallenged until after 1950, was seriously upset in 1958 by the discoveries of Alfred Dürr and Georg von Dadelsen; and the consequences of the new chronology can be only slowly digested. Further, when Bach had the chance he would revise his works, perhaps two or three times; the date of the

final version (even if known) is therefore no clue to the date at which the broad outline of the work first came into his mind.

Bach inherited the mixed and rather old-fashioned musical culture of the Thuringian area, perhaps (through his brother, Johann Christoph) with a bias toward the orderly styles of the south. When circumstances took him to Lüneburg, he nevertheless learned eagerly from the northern rhapsodists, Buxtehude above all. By 1708 he had probably learned all that his German predecessors could teach him and arrived at a personal synthesis of northern and southern styles. He had also studied some French organ and instrumental music; but apart from a few alleged thematic borrowings there is little trace of French influence in Bach's music at any time of his life.

Among the few works that can be ascribed to these early years with anything more than a show of plausibility are the *Capriccio sopra la lontananza del suo fratello dilettissimo* (*Capriccio on the Departure of a Beloved Brother* [1704]); the chorale prelude on *Wie schön leuchtet* (*c.* 1705); the fragmentary early version (still unpublished) of the organ Prelude and Fugue in G minor (before 1707); Cantatas 131, 106 (?), 71, 196, 4 (?); and perhaps the organ Toccata and Fugue in D minor and Prelude and Fugue in D major.

As far as keyboard technique is concerned, Bach had already equaled the showiest of his predecessors (except possibly in organ double pedaling); but his keyboard writing was sometimes ungrateful. In rhapsodical writing (*see* above, the organ toccata) he was less violent than the average northerner and correspondingly more effective; he had already started on the path of increasing self-control that led through the *Chromatic Fantasia* and the organ *Fantasia* in G minor to the toccata of *Partita VI* (1725). Melodically there are traces of a desire for shapely expressive line, in the manner of the new school; but he had not yet broken away from the tricks of his predecessors, whose writing, even in fugue subjects, was riddled with repeated notes and changing-note formulas such as *e f e f, d e d e*. Repeated notes are also common in the declamatory vocal writing of the earliest cantatas (least noticeable in no. 4, where the voice parts are largely derived from a chorale). Rudiments of ritornello form can be detected here and there, but in movements of any size Bach generally obtained coherence (or a semblance of it) by fugue, motet form, or quasi-*ostinato* treatment. The organ Fugue in G minor, even in its early version, shows the concertolike division into sections with and without pedal, which is characteristic of the mature organ fugues; but preludial writing developed more slowly—the associated prelude is shapeless and ineffective.

The organ *Passacaglia*—a close imitation of Buxtehude, which cannot be much later than 1708—is worth mentioning as an early and amusing example of Bach's instinct for large-scale organization. To write a *passacaglia* of 168 bars on the traditional four-bar basses, a composer had to devise 41 variations (after stating the theme). The strain on the inventive faculty was very considerable, and was often lessened by such illogical devices as writing pairs of almost identical variations, metamorphosing the bass almost beyond recognition or even inserting what seem to be free interludes. Apparently it took Bach to see that with an eight-bar bass only 20 variations were necessary. His *Passacaglia* shows traces of the paired-variation device but otherwise is strictly logical, with neither free interludes nor unreasonable metamorphoses.

Most unfortunately, Bach's development cannot be traced in detail during the vital years 1708–14; there are too few datable works. From the series of cantatas written in 1714–16, however, it is obvious that he had been decisively influenced by the new school and the Italian concerto-composers, with results that have been mentioned already and can be seen in such cantatas as no. 182, 199, 61 (1714); 31, 161 (1715); and 208, 70, 147 (1716).

Among other works pretty certainly composed at Weimar are most of the *Orgelbüchlein;* all but the last of the so-called 18 Chorale Preludes; the earliest organ trios; and most of the organ preludes and fugues. The "Great" Prelude and Fugue in G major for organ (BWV 541) was finally revised about 1715, and the Toccata in F major may have been played at Weissenfels in 1714 or 1716. It has not yet been proved that any of the organ preludes and fugues were actually composed at Leipzig, though fair copies of the Preludes and Fugues in B minor and E minor ("The Wedge") were made about 1730.

The chief works of the Köthen period are listed above (see *Life*). Stylistically there does not seem to be any very notable change, partly, perhaps, because some of these works were composed at Weimar and only revised at Köthen.

As a result of the upheaval caused by the new chronology, it would be rash to attempt a detailed account of stylistic developments during Bach's earlier years at Leipzig; but the following hints may be useful. The lists of cantatas are far from complete, but they include works that are likely to be recorded.

In the early months of 1723 Bach produced Cantata 22, just possibly the *St. John Passion* (there is no real evidence for a performance before 1724) and perhaps one or two other works.

His first official performance was on May 30, 1723, the first Sunday after Trinity Sunday, with Cantata 75. New works produced during this year include Cantatas 76, 46, 77, 25, 95, 40; the motet *Jesu, meine Freude;* and the *Magnificat.* In these last two Bach toyed with the idea of unifying a work by making the last movement repeat or refer to the first. The idea does not seem to have appealed to him, though he returned to it in the motet *Fürchte dich nicht* (1726?), Parts II and III of the *Christmas Oratorio* (1734) and the *Goldberg Variations* (*c.* 1742). The first half of 1724 saw the production of Cantatas 65, 104, 166 and the *St. John Passion;* the latter was subsequently revised. The total number of cantatas produced during this ecclesiastical year was about 62, of which about 39 were new works.

On June 11, 1724, the first Sunday after Trinity, Bach began a fresh annual cycle of cantatas, and within the year he wrote 52 of the so-called chorale cantatas, formerly supposed to date from 1735–45. The chorale cantatas of 1724 include no. 20, 135, 10, 93, 8, 180, 38, 116 and 91. The Sanctus of the *B minor Mass* was produced at Christmas. Chorale cantatas of the first half of 1725 include no. 125, 127, 6, 87, 68, 175 and 176.

For the later months of 1725, only about nine cantatas have been preserved; these include no. 110 and 151. In 1726 Bach lightened the burden of composition by producing 18 cantatas by Johann Ludwig Bach, but also performed such works as Cantatas 13, 43, 45, 17, 27, 169 and 49. After this he lost interest in church cantatas, for reasons suggested above (see *Life* above); no. 140 (1731) and 14 (1735) are among the comparatively few that can be definitely dated after 1730. He did, however, produce the *St. Matthew Passion* in 1729 (like the *St. John,* it was subsequently revised) and a *St. Mark Passion,* which has disappeared, in 1731. It must also be remembered that the *Christmas Oratorio* is in fact a sequence of six cantatas.

Of the other Leipzig works, the most important have been mentioned under *Life,* above. Very tentatively, one may suggest that the works of this period show the following tendencies: (1) the themes and melodic lines become less broadly singable; they seem to be conceived more in terms of orchestral (not, as a rule, keyboard) instruments; (2) the harmony becomes smoother and more academic; various asperities in the E flat *Magnificat* of 1723 were removed in the D major revision of *c.* 1730; (3) about 1740, following (or perhaps anticipating) current taste, Bach began to exhibit an interest in elaborate counterpoint. He continued to "write otherwise when he wanted to," as in the third movement of the sonata in *The Musical Offering,* perhaps his most remarkable piece of *galanterie* (1747); but the characteristic compositions of these last years are the canons of the *Goldberg Variations,* of the variations on *Vom Himmel hoch* and of *The Musical Offering,* with the canonic and fugal complexities of *The Art of Fugue.* To judge by the numerous corrections made in *Vom Himmel hoch,* the supreme contrapuntist did not find strict canon particularly easy.

Spurious Works.—The following works (among many others, for which *see* Wolfgang Schmieder's *Bach-Werke-Verzeichnis*) are more or less certainly spurious: the *St. Luke Passion;* the *Magnificat* for soprano solo; the motets *Ich lasse dich nicht* (*I Wrestle and Pray*) and *Lob, Ehr' und Weisheit* (*Blessing and Glory*); Cantatas 15, 141, 142, 160, 189, 218, 219; the organ Concerto

in E flat; the Eight Short Preludes and Fugues; and the two chorale preludes in C on *Ach Gott und Herr.* Although Bach knew that the letters of his own name represented notes and were musically significant, it is doubtful whether any of the fugues on those notes are authentic, except the unfinished movement in *The Art of Fugue.*

Editions.—C. S. Terry once remarked: "Bach's business mind was as orderly as his counterpoint." The truth probably is that it was a great deal more orderly. It is unlikely that Bach ever spent a penny without knowing where it went; but in dealing with his own music he was slovenly. The second part of the *Clavierübung* was published twice during his lifetime; neither edition is correct, and in places the second is worse than the first.

For a summary account of editorial problems in general, *see* Walter Emery, *Editions and Musicians,* 2nd ed. (1958). First editions and facsimiles of autograph manuscripts are not infallible guides to Bach's intentions. In fact, they are often dangerously misleading, and practical musicians should take expert advice before consulting them. Editions published between 1752 and *c.* 1840 are little more than curiosities, chiefly interesting for the light they throw on the progress of the revival.

No comprehensive edition is trustworthy throughout; neither Peters, nor the BG, nor even the NBA (*see* above, *The Revival*). Nevertheless, students of Bach will do well to begin by finding out whether the music they want has been published by the NBA.

The word *Urtext* (original text) may lead the uninitiated to suppose that they are being offered an exact reproduction of what Bach wrote. It must be understood that the autographs of many important works no longer exist and that the extant autographs are often wrong. As a rule, Bach's intentions have to be pieced together from anything up to 20 sources, all different, and all more or less wrong. The result may come very close to what Bach meant, but does not necessarily represent what he wrote; in a certain sense, and to a strictly limited extent, it has been composed by the editor. This is inevitable, because of the mistakes made by 18th-century copyists and engravers, and, above all, because of Bach's own carelessness.

Until and unless they are superseded by the NBA, the following editions can be recommended. The "Forty-eight," ed. by H. Bischoff; the *Inventions, English Suites, Partitas, Italian Concerto* and *French Overture, Goldberg Variations* and *Gamba Sonatas,* in the Peters *Urtext* edition; the *St. John Passion,* ed. by A. Mendel; *The St. Matthew Passion* (in German), ed. by Max Schneider; the *Organ Sonatas* and *Orgelbüchlein,* ed. by John Dykes Bower and Walter Emery; *The Cantatas,* recent Breitkopf editions. *See* also Index references under "Bach, Johann Sebastian" in the Index volume.

Bibliography.—Up-to-date chronological information is available only in German. *See* Alfred Dürr, *Zur Chronologie der Leipziger Vokalwerke J. S. Bachs* (1958), and Georg von Dadelsen, *Beiträge zur Chronologie der Werke Johann Sebastian Bachs* (1958).

Thematic Index: W. Schmieder, *Thematisch-systematisches Verzeichnis der musikalischen Werke von J. S. Bach* (1950).

Documentary Biography: H. T. David and A. Mendel, *The Bach Reader* (1946).

Karl and I. S. Geiringer, *The Bach Family* (1954), is a good general summary, with a long section on J. S. Bach, and a useful bibliography. The following works are worth noting: A. E. F. Dickinson, *The Art of J. S. Bach,* 2nd rev. ed. (1951); J. N. Forkel, *J. S. Bach: His Life, Art and Work,* trans. by C. S. Terry (1920); also in *The Bach Reader;* Harvey Grace, *The Organ Works of Bach* (1923); Hermann Keller, *Die Orgelwerke Bachs* (1948), *Die Klavierwerke Bachs* (1950); G. Kinsky, *Die Originalausgaben der Werke J. S. Bachs* (1937); W. Neumann, *Handbuch der Kantaten J. S. Bachs,* 2nd rev. ed. (1953); A. Schweitzer, *J. S. Bach,* trans. by E. Newman, 2 vol. (1911); P. Spitta, *Johann Sebastian Bach, His Work and Influence on the Music of Germany, 1685–1750,* trans. by C. Bell and J. A. Fuller-Maitland, 3 vol. (1883–85); C. S. Terry, *Bach,* 2nd. rev. ed. (1933); *Bach's Chorals,* 3 vol. (1915–21); *J. S. Bach: Cantata Texts, Sacred and Secular* (1926); D. F. Tovey, *A Companion to "The Art of Fugue"* (1931).

For the motets *see* W. G. Whittaker, *Fugitive Notes on Certain Cantatas and the Motets of J. S. Bach* (1924). For Bach's "modernity," *see* H. Besseler's contribution to *J. S. Bach in Thüringen* (1950), and Winfried Schrammek's article in *Bach-Jahrbuch* (1954). For symbolism, *see* W. Emery, "A Rationale of Bach's Symbolism" in *The Musical Times* (Oct. and Nov. 1954); H. Schwarzschild, "New Light on the Forty-eight" in *The Musical Times* (April 1956); and R. F. T. Bullivant, "Word-painting and Chromaticism in the Music of J. S. Bach" in *The Music Review* (Aug.–Nov. 1959).

For problems of performance *see* C. P. E. Bach, *Essay on the True Art of Playing Keyboard Instruments,* trans. and ed. by W. J. Mitchell 2nd ed. (1951); Walter Emery, *Bach's Ornaments* (1953); the preface to A. Mendel's edition of the *St. John Passion* (1951); and W. G. Whittaker (*see* above). There is no adequate discussion of the important but highly controversial question of how far the rhythmic conventions of the period (double-dotting, etc.) apply to Bach; but the chief possibilities are mentioned in Arnold Dolmetsch, *The Interpretation of the Music of the 17th and 18th Centuries* (1915) and in the article *Inégales* by Robert Donington in G. Grove, *Dictionary of Music and Musicians,* 5th ed. (1954). *See* also Sol Babitz, "A Problem of Rhythm in Baroque Music" in the *Musical Quarterly* (Oct. 1952). For continuo-playing *see* A. Mendel's preface (above), and F. T. Arnold, *The Art of Accompaniment From a Thorough-Bass as Practised in the XVIIth and XVIIIth Centuries* (1931). The following books make stimulating reading but need to be used with the greatest caution: W. G. Whittaker, *The Cantatas of Johann Sebastian Bach, Sacred and Secular,* 2 vol. (1959), and Erwin Bodky, *The Interpretation of Bach's Keyboard Works* (1960). (W. E.)

BACHAUMONT, the name of two French writers.

François Le Coigneux de Bachaumont (or Bois-Chaumont: 1624–1702) began a career in the *parlement* of Paris but resigned early for a life of ease. He is remembered as the originator of the name Fronde for the malcontents of 1648 and as co-author, with Chapelle (Claude Emmanuel Luillier), of the *Voyage de Chapelle et de Bachaumont,* a book of light verse and prose describing a journey through the south of France with much wit and occasional satire. First printed in 1663, the *Voyage* went through many editions, under varying titles, in the ensuing 200 years (modern ed. by D. Jouaust, 1874).

Louis Petit de Bachaumont (1690–1771), born in Paris on June 2, 1690, attached himself about 1730 to a widow, Mme Doublet (née Legendre), over whose *salon* he presided until his death (April 29, 1771). He recorded news and gossip of all sorts and circulated manuscript bulletins to subscribers. These bulletins were forbidden, but he still kept two registers, one for facts and one for rumours, incorporating anything that he thought to be of literary, theatrical, worldly or scandalous interest. The *Mémoires secrets pour servir à l'histoire de la république des lettres en France,* 36 vol. (1777–89), began with the posthumous publication of his material for the years 1762–71 (6 vol.); the following years, to 1787, were covered by continuators.

Bachaumont is most enjoyably read in selections. His tone is that of the contemporary Philosophes, skeptical and urbanely subversive. (J. G. R.-S.)

BACHELLER, IRVING ADDISON (1859–1950), U.S. novelist, the setting of whose books is generally upper New York state, was born in Pierpont, N.Y., on Sept. 26, 1859. He graduated from St. Lawrence university, Canton, N.Y., in 1882 and entered journalism. In 1883 in Brooklyn, N.Y., he founded the first modern newspaper syndicate and through its services distributed fiction by such writers as Joseph Conrad, Rudyard Kipling and Stephen Crane, as well as non-fictional material. From 1898 to 1900 he was editor of the *New York World.* Bacheller became extremely popular as a writer of fiction, being known especially for *Eben Holden: a Tale of the North Country* (1900), which sold over 1,000,000 copies. This novel about a hired man gives an authentic picture of 19th-century farm life and character in upper New York state. *D'ri and I* (1901), a novel about the battle of Lake Erie in the War of 1812, was also popular. His 31 published works are generally humorous and full of penetrating character delineations, especially of rural types. His own favourites were *The Light in the Clearing* (1917) and *A Man for the Ages* (1919), a story of Lincoln. *Opinions of a Cheerful Yankee* (1926), *Coming up the Road: Memories of a North Country Boyhood* (1928) and *From Stores of Memory* (1938) were autobiographical. He died at White Plains, N.Y., Feb. 24, 1950.

BACHELOR, a word derived from the medieval Lat. *baccalaris,* which seems originally to have designated a vassal of very low rank in the feudal hierarchy but soon to have been extended to men of subordinate position in other systems. Similarly, bachelor has been applied to various categories of persons as follows: (1) ecclesiastics of an inferior grade, for instance young monks or even recently appointed canons; (2) those belonging

to the lowest stage of knighthood (*see* KNIGHTHOOD, CHIVALRY AND ORDERS); (3) those holding the preliminary degree of a university, enabling them to proceed to that of master which alone entitled them to teach (in modern universities the degree of bachelor, which moreover may also be held by women, varies in its significance as a step toward other degrees, but in no case is the bachelor a full member of the university); (4) the younger or inferior members of a trade guild or city company, otherwise known as yeomen (now obsolete); (5) unmarried men, since these presumably have their fortunes yet to make.

Bachelors, in the sense of unmarried men, have in many countries been subjected to penal laws. In ancient Greece, at Sparta, citizens who remained unmarried after a certain age suffered various penalties, and at Athens, though there was no definite legislation on this matter, certain minor laws were evidently dictated by a spirit akin to the Spartan doctrine. At Rome, the *lex Julia et Papia Poppaea,* while restricting marriages between the several classes of the people, laid heavy penalties on unmarried persons, gave certain privileges to citizens with several children and imposed lighter penalties on married persons who were childless. Isolated instances of such penalties occur in western Europe during the middle ages. In Great Britain there has been no direct legislation bearing on bachelors, but occasionally taxes have been made to bear more heavily on them than on others; *e.g.*, two acts of 1695, which taxed bachelors to pay for the war with France, and the income tax of 1799, which also differentiated against bachelors. Since 1908, moreover, the British income tax law, by giving special abatements to men of family, has in effect taxed bachelors. The U.S. income tax law has a like effect. In Italy this principle was carried further by the Fascist governments under Mussolini, which imposed taxation directly on unmarried men.

BACHMAN, JOHN (1790–1874), U.S. naturalist and minister, most famous for his work with John James Audubon (*q.v.*), was born Feb. 4, 1790, in Rhinebeck, N.Y. He became a Lutheran minister in 1813 and founded both the Lutheran Synod of South Carolina, of which he was first president, and the state's Lutheran Theological seminary. Bachman wrote most of the Audubon-illustrated *Viviparous Quadrupeds of North America* and assisted Audubon in the preparation of his book on American birds. He was also the author of numerous other works on both nature and religion. He died in Columbia, S.C., Feb. 24, 1874.

See J. B. Haskell and C. Bachman, *John Bachman . . . Letters and Memories of his Life* (1888).

BACHOFEN, JOHANN JAKOB (1815–1887), Swiss anthropologist and jurist, was born in Basel, Dec. 22, 1815. He is remembered almost solely for *Das Mutterrecht* (1861), in which he challenged, for the first time, the prevailing patriarchal theory of social evolution. (*See* MATRILINY.) Having found evidence of matrilineal descent in ancient Greece and among primitive peoples of Africa and America, he formulated the following theory of social evolution: In the beginning a condition of promiscuity prevailed. This was followed by matriarchy. Then men gained the ascendancy and patriarchy was permanently established. Bachofen conceived of these sequences as universal stages of social evolution. He was correct in arguing for matrilineal descent, but matriliny is not matriarchy, and no society in which women were predominant has ever been found. The theory of primordial promiscuity has been shown to be invalid. Finally, Bachofen's sequences cannot be regarded as universal stages of evolution. However, by demonstrating the existence and prevalence of matrilineal descent, Bachofen exerted a salutary influence upon ethnological theory and research.

Bachofen was educated in Basel, Berlin, Cambridge and Paris. From 1841–45 he was professor of Roman law at the University of Basel, and from 1842 a judge in the criminal court of that city.

BIBLIOGRAPHY.—Bachofen's *Gesammelte Werke,* ed. by Karl Meuli, 10 vol. (1943 ff.), especially *Das Mutterrecht,* 2 vol. (1948), with biography of Bachofen and an analysis of his work; Heinrich Cunow, "Bachofen, J. J." in *Encyclopaedia of the Social Sciences* (1930), with bibliography; Robert H. Lowie's appraisal in *The History of Ethnological Theory* (1937) and his review of the 1948 edition of *Das Mutterrecht, Amer. Anthrop.*, vol. 51, pp. 628–629 (1949).

(LE. A. W.)

BACICCIO (GIOVANNI BATTISTA GAULLI) (1639–1709), Italian painter, whose frescoes exemplify the most ambitious decorative style of the Roman baroque, was born on May 8, 1639, in Genoa where, a pupil of Luciano Borzone, he was also influenced by Van Dyck and Bernardo Strozzi. He moved to Rome about 1660. A visit to Parma in 1669, to study the frescoes of Correggio, left some mark on his style, but the chief formative influence upon him was that of Bernini, who befriended the young painter and introduced him to his circle of Roman patrons.

Baciccio's principal works are his fresco decorations in the Roman churches Sta. Agnese in the Piazza Navona (1668–71), the Gesù (finished 1683) and SS. Apostoli (1707). In these, and particularly in the Gesù, where Antonio Raggi's stuccoes are said to have been based on Baciccio's designs, he combined an ecstatic religious figure-style, derived from Bernini, and a melting, sensual treatment of the heads, derived from Correggio, with his own masterly organization of masses of light and shade and an attractive bravura of execution. He also painted altarpieces for various Roman churches and was well known as a portraitist of the papal circle. He died in Rome on April 2, 1709.

See R. Wittkower, *Art and Architecture in Italy 1600–1750* (1958).

(D. KG.)

BACILLARIOPHYCEAE: *see* DIATOMS.

BACILLUS, a genus of rod-shaped, spore-forming, aerobic bacteria of the family Bacillaceae, order Eubacteriales. Of the 25 or more species differentiated, relatively few are disease producing. *Bacillus anthracis* is the causative agent of anthrax (*q.v.*). *Bacillus larvae* and *B. alvei,* the causative agents of American and European foul brood of bees, respectively, do not cause disease in man (*see* BEEKEEPING); a few other species that cause disease in certain insect pests are used as biological control (*see* ENTOMOLOGY: *Principles of Insect Control*). Most of the other species of *Bacillus* are harmless saprophytes occurring in air, soil and dust; but one, *Bacillus subtilis,* is a rare cause of conjunctivitis in man.

The term bacillus is sometimes applied to any rod-shaped bacteria.

See BACTERIA. (W. BU.; X.)

BACK, SIR GEORGE (1796–1878), British explorer and sailor, who helped trace the North American arctic coast line, was born in Nov. 1796 at Stockport in Cheshire. Back entered the navy as a midshipman in 1808 and fought against the French in Spain and in North America. He was a member of Capt. D. Buchan's expedition of 1818 to Spitsbergen, sailing in the "Trent" under Lieut. J. Franklin; afterward he joined Franklin in exploring the Coppermine river in North America (1819–22) and the Mackenzie river (1825–27). Back offered, in 1833, to search for Capt. J. Ross, of whose arctic expedition nothing had been heard since 1829. He wintered at Ft. Reliance, near the Great Slave lake, where in April 1834 he heard that Ross had returned to England. Back, however, proceeded to explore the Great Fish river (later renamed the Back river), tracing it to its mouth on the Arctic ocean. On his return in Oct. 1835, he received the medal of the Royal Geographical society. He sailed in the "Terror" in 1836 to explore the North American coast line, from Repulse bay to the mouth of the Back river; but the ship was icebound for four months, and he returned in Sept. 1837 with his task unaccomplished. Back was prevented by ill-health from further activity. He was knighted in 1839 and was made an admiral in 1857. He died in London, on June 23, 1878.

He wrote *Narrative of the Arctic Land Expedition to the Mouth of the Great Fish River* (1836), and *Narrative of an Expedition in H.M.S. Terror* (1838).

BACK BOND (BACK LETTER), in Scots law, a deed qualifying the terms of another deed or declaratory of the purposes for which another deed has been granted. In Scotland, building societies usually take security in the form of an apparently absolute conveyance qualified by a back bond which expresses the limitation on their right and states the redemption terms. The transaction resembles the English deed of trust, and similar qualifying instruments are known in other countries. (M. C. ME.)

BACKBONE: *see* SKELETON, VERTEBRATE; SPINE, DISEASES

AND DISABILITIES OF; VERTEBRATE.

BACKGAMMON, a game of moving counters on a board or table, the object of the game being a race to a goal, and the movement of the counters being controlled by the throw of two dice. The elements of chance and skill are nicely balanced in backgammon so that each is usually essential to victory.

Precursors of backgammon are among the most ancient of all games. A playing board suitable for backgammon, found at Ur of the Chaldees, may date from as early as 3000 B.C. The ancient Greeks and Romans played a game, *ludus duodecim scriptorum* ("twelve-lined game"), which was identical or nearly so with modern backgammon. The game is still most generally played in the eastern Mediterranean countries. Oriental equivalents of backgammon are generally thought to be importations from the west, despite legends to the contrary. Those who place the invention of backgammon in the 10th century probably refer to the change from a board resembling the one used in pachisi (Indian precursor of parcheesi) to the present type. In early English writing, backgammon was "a game played within the tables," or more simply "tables"; Chaucer alludes to such a game. The many past variants of backgammon include Irish, ticktack (from *trictrac,* the French name for backgammon, imitative of the rattle of the dice), and many European, African and oriental games. In England Edmond Hoyle codified the rules and strategy of backgammon in 1743 and there has been little significant change, except for the introduction of "doubling," which produced a renascence of interest in backgammon about 1925.

AFTER THE LOUTERELL PSALTER

A GAME OF BACKGAMMON OR "TABLES" IN MEDIEVAL ENGLAND

Method of Play.—Backgammon is played by two persons, but three or more may participate in the stakes by chouette, that is, by one player agreeing to take all bets. The board (*see* diagram) comprises four sections, or tables, each marked with six narrow wedges, or points, in two alternating colours. The division between the inner and outer tables is the bar. The pieces, often called stones, are 15 white and 15 black draftsmen. The initial position is shown in the diagram. There is no standard notation, but the general practice is to consider the points on each side of the board as numbered from 1 to 12, from inner to outer table beginning with the ace point. The two stones initially posted on the adversary's 1-point, and also any stones subsequently placed in the adversary's inner table, are often called runners.

Each player has two dice and a dicebox. To commence a game, each casts one or two dice, as agreed, and the higher throw marks the first player. The latter either adopts the numbers thrown or, according to local custom, casts again, using both his own dice. Thereafter the players alternately cast both dice and move the stones accordingly. The movement is in opposite directions, from adversary's inner table to adversary's outer, thence to own outer, finally to own inner table and "off." The stones are moved from point to point, the exact number of points shown on the dice. The two numbers may be applied separately to two different stones or, in turn, to one. Doublets (identical numbers on the two dice) are taken twice over; *e.g.,* two sixes count as four sixes, making a total of 24 points traversed.

A point occupied by two or more stones of one colour is made by that player and cannot be occupied by the opponent. Any other point is open. The advance of a stone is legal only if it lands on a point not made by the opponent. When both numbers are applied to one stone, each is played separately and both landing places in its advance must be open. There is no limit to the number of stones that a player may pile on a point made by himself. A player must use both of his numbers if able and either number may be played first; but if he can use only one number he must use the higher if able. If he cannot use either, the turn passes.

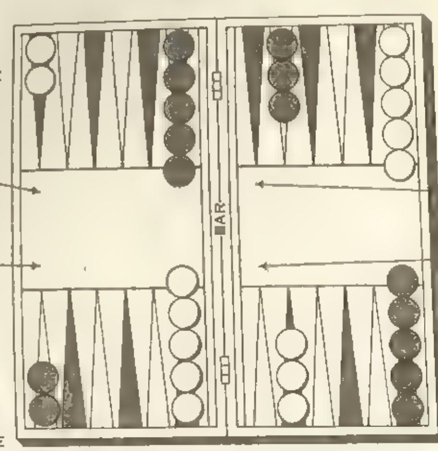
A single stone on a point is a blot, liable to be hit (or taken up) by an adverse stone landing on that point. If hit, a blot is picked up and placed literally on the bar, and the owner may make no other move until it is re-entered. Re-entry must be made in the adverse inner table, upon an open point of the same number as is cast with either die. A stone may re-enter and move in the same turn; *e.g.,* on the cast of 6–5, it may be entered on the adverse 5-point (if open) and then moved to the adverse 11-point. When a player makes all six points in his inner table he has a shutout; if he then hits an adverse blot, he alone continues to roll his dice until such time as he opens a point in the shutout and so affords his opponent possible entry. Making six adjacent points elsewhere than in one's own home table is called a side prime or prime; obviously, since each number cast is played separately and must land on an open point, it prevents the escape of adverse runners trapped behind it.

On getting all 15 of his stones into his own home table, a player may begin bearing off. This process is equivalent to continuing their movement in the same direction, upon imaginary points beyond the edge of the board. Once borne off, a stone stays off the board, but if a blot is hit (by an adverse stone in one's home table) it must be placed on the bar, re-entered and brought around to the home table again before bearing can be resumed. The player who first bears off all 15 stones wins the game. If the loser has borne off at least one stone, the game is a single; if he has borne none, it is a gammon and counts double, and if in addition he has any stone left in the winner's inner table, it is a backgammon and counts triple.

Doubling.—Backgammon is played for an agreed base stake, and modern practice is to allow voluntary doubling of stakes during the play. Either may offer the first double; thereafter the right to double alternates. A player may resign and pay the current stake, when a double is proposed by his opponent, in preference to playing on at the doubled stake. Gammon or backgammon further doubles or triples the stake. In addition, some allow automatic doubles. When the roll for first turn is a doublet, the stake is doubled; such automatic doubles are usually limited by agreement to one or two.

The Rules of Play.—According to Hoyle, a piece touched by the caster must be moved if possible, and a move is irrevocable after the piece is quitted. Modern club practice is to allow the caster to change his moves until he has picked up his dice. An incorrect move must be rectified on demand, but stands if the next roll has been made. If a die is cocked, both must be cast again (a die is cocked if it does not rest squarely on one face).

The Chief Principles of Play.—(1) To make points where they will have the best chance of obstructing the opponent. At the outset, the most valuable points to make are considered to be one's own 5-point, own 7-point (called the bar point) and adverse 5-point. (2) To minimize the hazard in leaving blots. The degree of risk that can be accepted in blotting is proportionate to the



A MODERN BACKGAMMON BOARD WITH PIECES IN POSITION AT THE BEGINNING OF PLAY

In addition to this special board, two dice are required to play the game

number of points open in the adverse inner table, and the opponent's prospects of making a prime, etc. If a blot must be left, it is evidently safer seven or more points away from its attacker than six or less. Exact odds on various plays can usually be calculated quickly as there are only 36 possible permutations of the two dice. (*See* Dice: *Probabilities*.)

For example, of the 36 possible rolls, 11 contain an ace, for an ace on either of two dice may be combined with any of five numbers on the other, making 10 different rolls, and the 11th roll is the doublet 1–1. The odds are thus 25 to 11 that a player will not roll an ace. In the same manner one learns that the odds of 25 to 11 apply when it is necessary to enter the opponent's inner table with only one of its points open.

Centuries of analysis have established certain moves as best to make on opening throws. In the following summary of these

First Throw	White's Move
6-5	B1-B12
6-4	B1-B11
6-3	B1-B10
6-2	B1-B9 or B12-W5
6-1	{ B12-W7, W8-W7 }
5-4	B1-B10 or { B1-B5, B12-W8 } or { B12-W8, B12-W9 }
5-3	{ W6-W3, W8-W3 } or { B12-W8, B12-W10 }
5-2	{ B12-W8, B12-W11 }
5-1	{ B12-W8, B1-B2 }
4-3	{ B12-W9, B12-W10 } or { B12-W9, B1-B4 }
4-2	{ W8-W4, W6-W4 }
4-1	{ B12-W9, B1-B2 }
3-2	{ B12-W10, B12-W11 } or { B12-W10, B1-B3 }
3-1	{ W8-W5, W6-W5 }
2-1	{ B12-W11, B1-B2 } or B12-W10

moves, it is White's first play. The notation B12-W7, would indicate that White moves one man from Black's 12-point to White's 7-point, and so forth, (see *Method of Play,* above). The classic move is given first; in some cases it is followed by an alternative move which is preferred by modern expert players.

When a player casts doublets on his first throw, his best play (if his opponent's previous move has not made it impossible) is considered to be as follows. In each case, two pieces are moved at a time:

Doublet	Move
1-1	{ W6-W5, W8-W7 }
6-6	{ B1-B7, B12-W7 }
5-5	B12-W3
4-4	B12-W5 or (a) { B12-W9, B1-B5 } or (a) B1-B9
3-3	B12-W7 or (a) { W8-W5, B1-B4 } or (b) { W8-W5, W6-W3 }
2-2	(a) B1-B5 or (c) { B1-B3, W6-W4 } or { B12-W11, W6-W4 }

(a) If Black has made his bar-point.
(b) Favoured by modern experts.
(c) If Black has made his 5-point.

Russian Backgammon.—This varies from the above game in that all stones are originally off the board, are entered in the same table and travel concurrently around to the same home table. Variants differ as to other rules. The first stone entered may be moved thereafter, or two men must be entered before moving.

Blots may be hit at any time; a blot must be re-entered before making any other move. Doublets are used twice over, together with the doublets on the opposite faces (opposite faces of a die total seven); sometimes the opposite doublets may be used first, and sometimes the caster may roll a second time after throwing doublets. This privilege is lost if he cannot use all of his first roll, and sometimes his opponent is allowed to use what he cannot. Complementary doublets and the second roll are usually barred on the first turn.

Acey Deucey.—This is a variant in which the roll of 2–1 gives special privileges, as choice of any doublet and a second turn. The rules differ widely in various localities. It is usual to begin with all men off the board, as in Russian backgammon.

Bibliography.—Edmond Hoyle, *A Short Treatise on the Game of Backgammon* (1743); *Laws of Backgammon* (1931), prepared by the Racquet and Tennis Club, New York; Albert H. Morehead and others, *The New Complete Hoyle* (1956). (G. Mh.; F. Hn.)

BACKHAUS, WILHELM (1884–), German pianist, best known for his interpretation of the works of Beethoven. Born March 26, 1884, at Leipzig, he studied there with A. Reckendorf and later with Eugen d'Albert in Frankfurt am Main. His first concert appearance was at the age of 8, and at 16 he made his first appearance abroad, in London. In 1905 he won the Rubinstein prize in Paris, and from 1912 to 1914 he toured the United States. He has held several teaching appointments: in 1905 he taught at the Royal Manchester College of Music, and played often with the Hallé orchestra under Hans Richter, who turned his attention to the music of Brahms. He also taught at Sondershausen (1907) and at the Curtis institute, Philadelphia (1925). After World War II he settled in Lugano in Switzerland but continued to spend his time touring and also recording. His style is marked by the devotion with which he subordinates his brilliant technique to the expression of the composer's intention, and by a clarity of tone that never lacks warmth. His remarkable memory has become legendary.

BACKHUYSEN (Bakhuysen, Backhuizen), **LUDOLF** (1631–1708), Dutch painter, celebrated for his sea pieces, was born on Dec. 18, 1631, at Emden, Hanover. He studied under Allart van Everdingen and Hendrik Dubbels. His numerous compositions are nearly all variations of one subject, and in a style peculiarly his own, marked by intense realism. In his later years Backhuysen employed his time in etching and calligraphy. He died in Amsterdam on Nov. 17, 1708.

BACK RIVER, formerly Great Fish river, in Mackenzie and Keewatin districts, Northwest Territories, Can., rises in a small lake about 120 mi. northeast of eastern Great Slave lake, at a height of about 1,280 ft. above sea level.

Named for Capt. (later Sir George) Back who descended the river to Chantrey inlet on the Arctic ocean in 1834, it is the longest river (605 mi.) in the Barren Grounds, but is not a usable waterway because of numerous rapids and falls. There is a tortuous upper course to Beechey lake. Downstream the flow slackens and the river leads through large sand areas containing Pelly, Garry and Macdougall lakes. From there it descends 450 ft. in 220 mi. through hill country.

Back river receives most of its tributaries from the south. Its largest tributary, Hayes river, enters south of Chantrey inlet from the east. There is a Roman Catholic mission for the inland Eskimos at Garry lake. (An. Kr.)

BACKUS, ISAAC (1724–1806), U.S. religious leader and historian, was born in Norwich, Conn., Jan. 9, 1724. Although he did not attend a college or religious seminary, he was awarded an honorary degree by Rhode Island college (now Brown university) in 1797. He was a controversial figure in religious disputes and for many years as an itinerant preacher in Massachusetts and Connecticut carried on his fight for religious freedom. He became the leading spokesman for the Baptist church. As historian, his leading contribution was *A History of New England, With Particular Reference to the Denomination of Christians Called Baptists*, published in three volumes (1777–96). A revision, edited by David Weston, was published in 1871. (E. E. R.)

BACOLOD, CITY OF, a chartered city and capital of Negros Occidental province, Philippines, lies on the western side of Negros Island, opposite the small island of Guimaras. Pop. (1960) 119,169. A paved coastal highway extends both north and south from the city.

A regional trade centre 330 mi. S.E. of Manila and the largest urban unit on the island, Bacolod has expanded rapidly. Since 1918 its population has progressively grown and in 1960 the increase was 17% above the 1948 census figure. This growth is explained, in part, by the fact that it is the capital of the wealthiest province and centrally located within the nation's most im-

portant sugar-producing area.

Bacolod lies on a flat coastal plain amid rice paddies and cane fields. It has a rectangular street pattern, unusual in Philippine coastal communities. In the northern part of the city are the large concrete capitol building, set amid spacious landscaped grounds; a 100-bed provincial hospital; and the provincial high school. The stone church and convent are on the plaza in the central business district.

The airport is at the southern limits of the city. The nearest sugar central (mill) is $1\frac{1}{2}$ mi. from the coast. There are many modern residences, owned by wealthy planters. The vernacular is a dialect of Visaya (Bisaya). (AN. C.)

BACON, FRANCIS, BARON VERULAM, VISCOUNT ST. ALBANS (1561–1626), lord chancellor of England, philosopher and man of letters. He long failed to attain in politics a position consonant with his birth and ability, ultimately owing his tenure of office to his support of the doctrine of royal prerogative and to the patronage of George, duke of Buckingham, the king's favourite. His position as a herald of the "new philosophy" (modern science) at the transition between medieval and modern thought, his breadth of vision and his pungency of style have made him more influential in the history of ideas than many greater philosophers. His *Essays* stand apart from his other writings and by their vivid aphoristic style would themselves ensure him a place in English literature.

LIFE

Francis Bacon was born on Jan. 22, 1561, in London; he was the younger son of Sir Nicholas Bacon, lord keeper, by his second wife Ann, daughter of Sir Anthony Cooke and sister-in-law of Sir William Cecil, Lord Burghley. In April 1573 he entered Trinity college, Cambridge. On June 27, 1576, he and his elder brother Anthony were admitted to Gray's Inn, but a few months later he went abroad with Sir Amias Paulet, the English ambassador to France. In 1579, after his father's death, he returned to England and took up residence at Gray's Inn, where he was admitted an outer barrister in 1582. Two years earlier he had applied unsuccessfully through his uncle, lord treasurer Burghley, for preferment in the royal service. In 1584 he was chosen member of parliament for Melcombe Regis in Dorset, and during the winter of 1584–85 he wrote a "Letter of Advice to Queen Elizabeth" which reveals a political judgment mature beyond his years and a coolness of temper considerably in advance of the times. In it he advocated not only a milder treatment of the Puritans but also, for Catholics, replacement of the oath of supremacy by an oath acknowledging that any Englishman would be a traitor if he refused to bear arms against any foreign enemy, the pope included.

In the 1586 parliament Bacon sat for Taunton and in that of 1589 for Liverpool, serving on a number of committees. Still lacking official preferment, he next attached himself, probably in 1591, to the queen's favourite, the young earl of Essex. He became one of Essex's confidential advisers and early in 1593 he drew his brother, Anthony, into the earl's service. However, in the parliament of 1593, when he sat for Middlesex, he seriously marred his prospects by his determined but untimely opposition to the government's demand for a triple subsidy to help to meet the expenses of the Spanish war. This conduct turned the queen against him and when the office of attorney general fell vacant she would not listen to Essex's enthusiastic advocacy of his claims. Instead, she appointed (1594) Sir Edward Coke, whom Burghley had supported. Even when, in the next year, Burghley joined Essex in recommending Bacon for the post of solicitor general, the queen still refused to appoint him, although she did make him one of her learned counsel.

Essex sought to make up for these disappointments by pressing upon him the gift of a piece of land at Twickenham. He also recommended him again—and again without success—for the post of master of the rolls. It seems, indeed, that this all-too-insistent advocacy was more of a hindrance than a help. Moreover, Bacon had begun to feel doubts about his patron's courses. Essex had always been attracted to an active career and enamoured of military renown. Also he was impetuous and easily provoked to rash actions when his counsels were resisted or rejected. In 1596, after the Cádiz expedition, he had become the idol of the military men and of the populace and Bacon saw clearly that for such a man to court such a reputation must assuredly alienate the queen's affections and arouse her fears. Accordingly he wrote (Oct. 1596) to Essex, urging him to seek the favour of the queen alone and to shun any appearance of popularity or of a "military dependency." His advice had little effect, for Essex was by then absorbed in the preparations against invasion and afterward, in 1597, with the Islands voyage. Bacon, who early in 1597 increased his reputation by the publication of a volume containing his first *Essays*, together with the *Colours of Good and Evil* and the *Meditationes sacrae*, remained on friendly terms with the earl and in 1598 was writing advice to him about Irish problems. After Essex's disgrace (1599), in consequence of his failure in Ireland and his unauthorized return to court, Bacon seems to have made some effort to mitigate the queen's wrath, but he also took a minor part, as one of her learned counsel, in accusing his patron at his informal trial before a body of privy councillors in June 1600. Essex bore him no ill will and shortly after his release was again on friendly terms with him. In Essex's desperate project of seizing the queen's person, forcing her to dismiss his rivals and rousing the city of London in his support, Bacon had neither share nor knowledge and after the abortive rebellion of Feb. 8, 1601, he played a prominent part, as queen's counsel, in the trial of the rebels, and helped considerably to secure Essex's conviction for treason. By thus biting the hand that had fed him, Bacon incurred much ill feeling, so much that in 1604 he published an *Apology* for his action. He had also been responsible for drafting in 1601 the official *Declaration of the Practices and Treasons Attempted and Committed by Robert, Late Earl of Essex*, though his draft was extensively altered and corrected by the queen and council. It is, of course, impossible to admire his conduct toward Essex; but it is only fair to remember that he often had warned the earl that "I love some things much better than I love your lordship, as the queen's service, her quiet and contentment, her honour, her favour, the good of my country and the like." Even so, his part in these actions and his efforts in the great monopolies debate of 1601 to guide the house of commons into courses not offensive to the queen did not win him any further advancement from Elizabeth. Nor did the accession of James I in 1603 bring immediate realization of his hopes. Through his cousin Robert Cecil he procured knighthood (July 1603). In 1604 he was confirmed as learned counsel and sat in the first parliament of the new reign as member for Ipswich, taking an active but not very successful part in the debates of its first session. He was also active as one of the commissioners for discussing a union with Scotland. In the autumn of 1605 he published his *Advancement of Learning*, dedicated to the king, and in the following summer he married Alice Barnham, the daughter of a London alderman. Preferment in the royal service, however, still eluded him, and it was not until June 1607 that his petitions and his vigorous though vain efforts to persuade the commons to accept the king's proposals for union with Scotland were at length rewarded with the post of solicitor general. Even then his political influence remained negligible, a fact which he came to attribute to the power and jealousy of Cecil, now earl of Salisbury and the king's chief minister. He had, however, not forgotten his project of reorganizing the study of natural science. He had surveyed the ground in the *Advancement of Learning;* and some short pieces not published at the time were probably written during the following two or three years. Toward the end of 1607 he sent to his friends a small tract entitled *Cogitata et Visa*, probably the first draft of the work now known under that title. In 1608 he wrote the panegyric *In felicem memoriam Elizabethae* and the learned and ingenious *De sapientia veterum*. He also completed what seems to have been the *Redargutio philosophiarum*, a treatise on the idols of the theatre.

After Salisbury's death (May 1612), Bacon renewed his efforts to gain influence with the king, writing a number of remarkable papers of advice upon affairs of state and, in particular, upon the relations between crown and parliament. The king did adopt his proposal for removing Coke from the common pleas to the king's

bench, transferring Sir Henry Hobart to the common pleas and putting Bacon in Hobart's place as attorney general (Oct. 1613). But, this apart, little heed was paid to his political advice, for James had fallen under the spell of Robert Carr (later earl of Somerset) and the Howards, while the "addled" parliament of 1614, in which Bacon sat for Cambridge university, showed an equal reluctance to listen to his counsels.

During the next few years, however, Bacon's views upon the royal prerogative brought him, as attorney general, increasingly into conflict with Coke, the champion of the common law and of the independence of the judges. It was Bacon who examined Coke when the king ordered the judges to be consulted individually and separately in the case of Edmond Peacham, a clergyman charged with treason as the author of an unpublished treatise justifying rebellion against oppression. It was he who instructed Coke and the other judges not to proceed in the case of commendams (holding of livings in the absence of the regular incumbent) until they had spoken with the king (*see* COKE, SIR EDWARD). Coke's dismissal (Nov. 1616) for defying this order was quickly followed by Bacon's appointment as lord keeper on March 7, 1617. It was largely to James's new favourite, George Villiers, later duke of Buckingham, that Bacon owed this advancement and also his promotion to be lord chancellor in Jan. 1618 and Baron Verulam in July. Yet Buckingham's favour still did not bring Bacon any real political influence and most of his time was still spent upon the judicial duties of his office. He displayed great energy as chancellor and also took a prominent part in the prosecutions of Sir Walter Raleigh (1618) and the earl of Suffolk (1619). Meanwhile he found time to enhance his fame by the publication in 1620 of his most celebrated work, the *Novum organum;* and on Jan. 27, 1621, he was created viscount St. Albans. Three days later parliament met for the first time since 1614 and soon the commons began to air their accumulated grievances, in particular against the king's grants of monopolies by patent. Bacon had earnestly pressed the king to recall the more obnoxious patents before parliament met but his advice had been ignored, and the commons then proposed to proceed against him as one of the referees who had certified that there was no legal objection to the grants. The proposal, however, was allowed to drop, probably because a more dangerous weapon was placed in the hands of his enemies. This was the accusation of bribery and corrupt dealings in chancery suits, an accusation apparently quite unexpected by Bacon but nevertheless the direct cause of his downfall. The charges against him rapidly accumulated and, giving up all idea of defense, he sent in a general confession of guilt. On May 3 the house of lords after considerable discussion decided upon the sentence, which was that he should undergo a fine of £40,000; that he should be imprisoned in the Tower during the king's pleasure; that he should forever be incapable of any office in the state; and that he should never sit in parliament, or come within the verge of the court. This sentence was executed only partially. The fine was in effect remitted by the king; imprisonment in the Tower lasted for about four days; a general pardon was made out and was passed in Oct. 1621. Bacon also received permission to come within the verge of the court, but he never sat again in parliament.

On the whole it appears that Bacon's own account of this painful episode is correct. He confesses (*Letters and Life*, vii, pp. 235–236) that he had received gifts from suitors involved in pending litigation. Yet he affirms that his intention was never swayed by a bribe; and in several cases his judgment appears to have been given against the party bestowing the bribe. Bacon was well aware that the practice was in itself indefensible. So far, then, as the mere taking of bribes was concerned, he would permit no defense, and his own judgment on his action contains as severe a condemnation as has ever been passed upon him. Yet he does not hesitate to call himself "the justest chancellor that hath been in the five changes since Sir Nicholas Bacon's time" (*Letters and Life*, vii, p. 560), on the plea that his intentions had always been pure and had never been affected by the presents received.

The remaining five years of his life were spent in work far more valuable to the world than anything he had accomplished in his high office. In March 1622 he presented to Prince Charles his *History of Henry VII.* In Nov. 1622 appeared the *Historia ventorum;* in Jan. 1623 the *Historia vitae et mortis;* and in Oct. the *De augmentis scientiarum,* a Latin translation, with many additions, of the *Advancement.* Finally, in 1625 he published his *Apophthegms* and *The Translation of Certain Psalms into English Verse,* dedicated to George Herbert; also, in 1625, a third and enlarged edition of the *Essays.*

His life then drew rapidly to a close. In March 1626, driving one day near Highgate and deciding on impulse to discover whether snow would delay the process of putrefaction, he stopped his carriage, purchased a fowl and assisted to stuff it with snow. He was seized with a sudden chill, considered to have brought on bronchitis, and died on April 9, 1626. (R. B. WM.)

BACON AS PHILOSOPHER AND STYLIST

Putting aside the letters and occasional writings, Bacon's works may be conveniently classified as professional, philosophical and literary, although it is impossible to consider him as a writer without considering his work as a whole, for he did not cease to be a stylist when he wrote philosophy nor abandon his philosophy, which indeed embodies his whole outlook on life, when writing even the most purely literary of his works, the *Essays.* The professional works include *The Learned Reading of Sir Francis Bacon Upon the Statute of Uses* (1642) and *The Elements of the Common Laws of England* (1630), part i of which consists of a collection of rules and maxims; part ii, on the use of the law, is probably not by Bacon. Bacon's legal writings exhibited a comprehensive intelligence of the abstract principles of jurisprudence, with a richness and ethical fullness that more than compensate for their lack of dry legal detail. Bacon seems to have been a lawyer of the first order, with a keen scientific insight into the bearings of isolated facts and a power of generalization which admirably fitted him for the self-imposed task, unfortunately never completed, of digesting or codifying the chaotic mass of the English law.

Philosophical Works.—The great mass of Bacon's philosophical writings consists of treatises or fragments, which either formed integral parts of his grand comprehensive scheme or were closely connected with it. More exactly they may be classified under three heads: writings originally intended to form parts of the *Instauratio* but which were afterward superseded or thrown aside; works connected with the *Instauratio* but not directly included in its plan; and writings which actually formed part of the *Instauratio magna.*

In the first group are some important tracts which certainly contain little, if anything, that was not afterward taken up and expanded in the more elaborate works but deserve attention because of the difference in the point of view and method of treatment. The most valuable are: (1) The *Advancement of Learning,* of which no detailed account need be given, as it is completely worked up into the *De augmentis* and takes its place as the first part of the *Instauratio.* Unlike most of Bacon's philosophical works, the *Advancement* was written in English. (2) *Valerius terminus,* a remarkable piece composed probably about 1603, though perhaps retouched at a later period. It contains a brief and somewhat obscure outline of the first two parts in the *Instauratio* and is of importance as affording some insight into the gradual development of the system in Bacon's own mind. (3) *Temporis partus masculus,* another curious fragment, remarkable not only for its contents but for its style, which is arrogant and offensive and in this respect unlike any other writing of Bacon's. (4) *Redargutio philosophiarum,* a highly finished piece in the form of an oration, composed probably about 1608 or 1609 and containing in considerable detail much of what afterward appeared in connection with the *Idola theatri* in book i of the *Novum organum.* (5) *Cogitata et visa,* perhaps the most important of the minor philosophical writings, dating from 1607 (though possibly the tract in its modern form may have been to some extent altered) and containing in weighty and sonorous Latin the substance of the first book of the *Organum.* (6) The *Descriptio globi intellectualis et thema coeli,* which is to some extent intermediate between the *Advancement* and the *De augmentis,* goes over in detail the general

classification of the sciences and enters particularly on some points of minor interest. (7) The brief tract *De interpretatione naturae sententiae duodecim* is evidently a first sketch of part of the *Novum organum*, and in phraseology is almost identical with it. (8) A few smaller pieces, such as the *Inquisitio de motu*, the *Calor et frigus*, the *Historia soni et auditus* and the *Phaenomena universi*, concerned respectively with motion, heat and cold, sound and natural phenomena, are early specimens of his *Natural History* and exhibit the first tentative applications of the new method.

The second group consists of treatises on subjects connected with the *Instauratio* but not forming part of it. The most interesting is the philosophic romance, the *New Atlantis*, a description of an ideal state in which the principles of the new philosophy are carried out by political machinery and under state guidance. The work was to have been completed by the addition of a second part, treating of the laws of a model commonwealth, which was never written. Another important tract is the *De principiis atque originibus secundum fabulas cupidinis et coeli*, where, under the disguise of two old mythological stories, Bacon (in the manner of *De sapientia veterum*) finds the deepest truths concealed. The tract is unusually interesting, for in it he discusses at some length the limits of science, the origin of things and the nature of primitive matter, giving at the same time full notices of Democritus among the ancient philosophers and of Telesio among the later ones. Deserving of attention also are the *Cogitationes de natura rerum*, probably written early, perhaps in 1605, and the treatise on the theory of the tides, *De fluxu et refluxu maris*, written probably about 1616.

Plan of the Instauratio.—In the third group the philosophical works which form part of the *Instauratio* must of course be classed according to the positions which they respectively hold in that scheme of the sciences. The great work, the reorganization of the sciences and the restoration of man to that command over nature which he was conceived to have lost by the fall of Adam, consisted in its final form of six divisions:

(1) *Partitiones scientiarum*, a survey of the sciences, either such as then existed or such as required to be constructed afresh—in fact, an inventory of all the possessions of the human mind. The famous classification on which this survey proceeds is based upon an analysis of the faculties and objects of human knowledge. (The division of the sciences adopted in the great French *Encyclopédie* was founded upon this classification of Bacon's; *see* ENCYCLOPAEDIA: *The French Encyclopaedists*.) This division is represented in the *Instauratio* by the *De augmentis scientiarum*.

(2) *Interpretatio Naturae.*—The new method, by which the mind of man is to be trained and directed in its progress toward the renovation of science. This division is represented, though only imperfectly, by the *Novum organum*, particularly book ii.

(3) *Historia Naturalis et Experimentalis.*—The new method is valueless, because inapplicable, unless it be supplied with materials duly collected and presented—in fact, unless there be formed a competent natural history of the *Phaenomena universi*. A short introductory sketch of the requisites of such a natural history, which according to Bacon is the *basis totius negotii*—the primary requirement—is given in the tract *Parasceve*, appended to the *Novum organum*. The principal works intended to form portions of the history, and either published by himself or left in manuscript, are *Historia ventorum, Historia vitae et mortis, Historia densi et rari* and the collection of facts and observations, *Sylva sylvarum*.

(4) *Scala Intellectus.*—It might have been supposed that the new philosophy could now be inaugurated. Materials had been supplied, along with a new method by which they were to be treated, and naturally the next step would be the finished result. But for practical purposes Bacon interposed two divisions between the preliminaries and the philosophy itself. The first was intended to consist of types or examples of investigations conducted by the new method, serviceable for keeping the whole process vividly before the mind or, as the title indicates, such that the mind could run rapidly up and down the several steps or grades in the process. Of this division there seems to be only one small fragment, the *Filum labyrinthi*.

(5) *Prodromi*, forerunners of the new philosophy. This part, strictly speaking, is quite extraneous to the general design. According to the *Distributio operis*, it was to contain certain speculations of Bacon's own, not formed by the new method but by the unassisted use of his understanding. These, therefore, form temporary or uncertain anticipations of the new philosophy. There is extant a short preface to this division of the work, and some of the miscellaneous treatises, such as *De principiis, De fluxu et refluxu maris, Cogitationes de natura rerum*, may have been intended to be included under this head. This supposition receives some support from the manner in which the fifth part is spoken of in the *Novum organum*, i, 116.

(6) The new philosophy, which is the work for future ages, and the result of the new method.

Bacon's Purpose.—Bacon's grand motive in his attempt to found the sciences anew was the intense conviction that the knowledge man possessed was of little service to him. "The knowledge whereof the world is now possessed, especially that of nature, extendeth not to magnitude and certainty of works." Man's sovereignty over nature, which can be founded on knowledge alone, had been lost, and instead of the free relation between things and the human mind there was nothing but vain notions and blind experiments. To restore the original commerce between man and nature and to re-establish the dominion of man (*imperium hominis*) is the grand object of all science. The want of success which had hitherto attended efforts in the same direction had been due to many causes but chiefly to the want of appreciation of the nature of philosophy and its real aim. The true philosophy is not the science of things divine and human; it is not the search after truth. "I find that even those that have sought knowledge for itself, and not for benefit or ostentation, or any practical enablement in the course of their life, have nevertheless propounded to themselves a wrong mark, namely satisfaction (which men call Truth) and not operation." "Is there any such happiness as for a man's mind to be raised above the confusion of things, where he may have the prospect of the order of nature and error of man? But is this a view of delight only and not of discovery? of contentment and not of benefit? Shall he not as well discern the riches of nature's warehouse as the beauty of her shop? Is truth ever barren? Shall he not be able thereby to produce worthy effects, and to endow the life of man with infinite commodities?" Philosophy is altogether practical; it is of little matter to the fortunes of humanity what abstract notions one may entertain concerning the ultimate nature and the principles of things. This truth, however, has never yet been recognized; it has not yet been seen that the true aim of all science is "to endow the condition and life of man with new powers or works," or "to extend more widely the limits of the power and greatness of man." Nevertheless, it is not to be imagined that by this being proposed as the great object of search there is thereby excluded all that has hitherto been looked upon as the higher aims of human life, such as the contemplation of truth. Not so, but by following the new aim we shall also arrive at a true knowledge of the universe in which we are, for without knowledge there is no power; truth and utility are in ultimate aspect the same; "works themselves are of greater value as pledges of truth than as contributing to the comforts of life."

Such was the conception of philosophy with which Bacon started and in which he felt himself to be thoroughly original. As his object was new and hitherto unproposed, so the method he intended to employ was different, he felt, from all modes of investigation hitherto attempted. "It would be," as he says, "an unsound fancy and self-contradictory to expect that things which have never yet been done can be done except by means which have never yet been tried." There were many obstacles in his way, and he seems always to have felt that the first part of the new scheme must be a *pars destruens*, a destructive criticism of all other methods. Opposition was to be expected, not only from previous philosophies but especially from the human mind itself. In the first place, natural antagonism must be looked for from the two opposed sects, the one of whom, in despair of knowledge, maintained that all science was impossible; while the other, resting on authority and on the learning that had been handed down from

the Greeks, declared that science was already completely known and consequently devoted their energies to methodizing and elaborating it. Secondly, within the domain of science itself, properly so-called, there were two "kind of rovers" who must be dismissed. The first were the speculative or logical philosophers, who construe the universe *ex analogia hominis* and not *ex analogia mundi*—or, in terms of their knowledge of man rather than of nature—who fashion nature according to preconceived ideas and who employ in their investigations syllogism and abstract reasoning. The second class, equally offensive, consisted of those who practised blind experience, which is mere groping in the dark (*vaga experientia mera palpatio est*), who occasionally hit upon good works or inventions, which, like Atalanta's apples, distracted them from further steady and gradual progress toward universal truth. In place of these straggling efforts of the unassisted human mind, a graduated system of helps was to be supplied by the use of which the mind, when placed on the right road, would proceed with unerring and mechanical certainty to the invention of new arts and sciences. Such were the peculiar functions of the new method, though it had not definitely appeared what that method was, or to what objects it could be applied.

The Idols.—Before proceeding to unfold his method Bacon found it necessary to enter in considerable detail upon the general subject of the obstacles to progress and devoted nearly the whole of the first book of the *Organum* to the examination of them. This discussion, though strictly speaking extraneous to the scheme, has always been looked upon as a most important part of his philosophy, and his name is perhaps as much associated with the doctrine of idols (*idola*) as with the theory of induction or the classification of the sciences. The doctrine of the kinds of fallacies or general classes of errors into which the human mind is prone to fall appears in many of the works written before the *Novum organum*, and the treatment of them varies in some respects. But the classification in the *Organum* has the author's sanction, and comparison of earlier notices, though a point of literary interest, has no important philosophic bearing. The *idola* (*Novum organum*, i, 39), false notions of things or erroneous ways of looking at nature, are of four kinds: the first two innate, pertaining to the very nature of the mind and not to be eradicated; the third creeping insensibly into men's minds and hence in a sense innate and inseparable; the fourth imposed from without.

The first kind is the *idola tribus*, idols of the tribe, fallacies incident to humanity or the race in general. Of these, the most prominent are the proneness to suppose in nature greater order and regularity than there actually is; the tendency to support a preconceived opinion by affirmative instances, neglecting all negative or opposed cases; and the tendency to generalize from few observations or to give reality to mere abstractions, figments of the mind. Manifold errors also result from the weakness of the senses, which affords scope for mere conjecture; from the influence exercised over the understanding by the will and passions; from the restless desire of the mind to penetrate to the ultimate principles of things; and from the belief that "man is the measure of the universe," whereas, in truth, the world is received by us in a distorted and erroneous manner. The second kind is the *idola specus*, idols of the cave, or errors incident to the peculiar mental or bodily constitution of each individual, for according to the state of the individual's mind is his view of things. Errors of this class are innumerable because there are numberless varieties of disposition; but some very prominent specimens can be indicated. These include the tendency to make all things subservient to or take the colour of some favourite subject; the extreme fondness and reverence for either what is ancient or what is modern; and excess in noting either differences or resemblances among things. A practical rule for avoiding these is also given: "In general let every student of nature take this as a rule, that whatever his mind seizes and dwells upon with particular satisfaction is to be held in suspicion." The third class consists of the *idola fori*, idols of the market place, errors arising from the influence exercised over the mind by mere words. This, according to Bacon, is the most troublesome kind of error and has been especially fatal in philosophy. For words introduce a fallacious mode of looking at things in two ways: first, there are some words that are really merely names for nonexistent things, which are yet supposed to exist simply because they have received a name; secondly, there are names hastily and unskilfully abstracted from a few objects and applied recklessly to all that have the faintest analogy with these objects, thus causing the grossest confusion. The fourth and last class is the *idola theatri*, idols of the theatre; *i.e.*, fallacious modes of thinking resulting from received systems of philosophy and from erroneous methods of demonstration. The criticism of the demonstrations is introduced later in close connection with Bacon's new method; they are the rival modes of procedure to which his own is definitely opposed. The philosophies which are "redargued" are divided into three classes, the sophistical, of which the best example is Aristotle, who, according to Bacon, forces nature into his abstract schemata and thinks to explain by definitions; the empirical, which from few and limited experiments leaps at once to general conclusions; and the superstitious, which corrupts philosophy by the introduction of poetical and theological notions. (In criticism of this famous analysis it may be mentioned that Bacon himself failed to discern a fifth set of idols, which may be termed the *idola academiae*, the idols of the schools, the fallacy of supposing that a blind though learned rule can take the place of judgment. It was this fifth idol that prevented Bacon from entering into the promised land of scientific discovery.)

The Importance of Natural Philosophy.—Such are the general causes of the errors that infest the human mind; by their exposure the way is cleared for the introduction of the new method. The nature of this method cannot be understood until it is seen exactly to what it is to be applied. What idea had Bacon of science, and how is his method connected with it? Now, the science which was specially and invariably contemplated by him was natural philosophy, the great mother of all the sciences; it was to him the type of scientific knowledge, and its method was the method of all true science. To discover exactly Bacon's view of the characteristics and the object of natural philosophy it is necessary to examine the place it holds in the general scheme furnished in the *Advancement* or *De augmentis*. All human knowledge, it is there laid down, may be referred to man's memory or imagination or reason. In the first, the bare facts presented to sense are collected and stored up; the exposition of them is history, which is either natural or civil. In the second, the materials of sense are separated or divided in ways not corresponding to nature but after the mind's own pleasure, and the result is poesy or feigned history. In the third, the materials are worked up after the model or pattern of nature, though we are prone to err in the progress from sense to reason; the result is philosophy, which is concerned either with God, with nature or with man. Natural philosophy is again divided into theoretical and practical, according as the end is contemplation or works. Theoretical natural philosophy has to deal with natural substances and qualities and is subdivided into physics and metaphysics. Physics inquires into the efficient and material causes of things; metaphysics into the formal and final causes. The principal objects of physics are concrete substances or abstract though physical qualities. The research into abstract qualities, the fundamental problem of physics, comes near to the metaphysical study of forms, which indeed differs from the first only in being more general and in having as its results a form strictly so-called; *i.e.*, a nature or quality which is a limitation or specific manifestation of some higher and better-known genus. Natural philosophy is, therefore, in ultimate resort the study of forms, and, consequently, the fundamental problem of philosophy in general is the discovery of these forms.

> On a given body to generate or superinduce a new nature or natures, is the work and aim of human power. . . . Of a given nature to discover the form or true specific difference, or nature engendering nature (*natura naturans*) or source of emanation (for these are the terms which are nearest to a description of the thing), is the work and aim of human knowledge.

Bacon's Concept of Forms.—The questions, then, whose answers give the key to the whole Baconian philosophy, may be put briefly thus—What are forms and how is it that knowledge of

them solves both the theoretical and the practical problem of science? Bacon himself, as may be seen from the passage quoted above, finds great difficulty in giving an adequate and exact definition of what he means by a form. As a general description, the following passage from the *Novum organum*, ii, 4, may be cited:

> The form of a nature is such that given the form the nature infallibly follows. . . . Again, the form is such that if it be taken away the nature infallibly vanishes. . . . Lastly, the true form is such that it deduces the given nature from some source of being which is inherent in more natures, and which is better known in the natural order of things than the form itself.

From this it would appear that since by a nature is meant some sensible quality, superinduced upon or possessed by a body, so by a form we are to understand the cause of that nature, which cause is itself a determinate case or manifestation of some general or abstract quality inherent in a greater number of objects. But all these are mostly marks by which a form may be recognized and do not explain what the form really is. A further definition is accordingly attempted in *Aphorism* 13:

> The form of a thing is the very thing itself, and the thing differs from the form no otherwise than as the apparent differs from the real, or the external from the internal, or the thing in reference to the man from the thing in reference to the universe.

This throws a new light on the question and from it the inference at once follows that the forms are the permanent causes or substances underlying all visible phenomena, which are merely manifestations of their activity. Are the forms, then, forces? At times it seems as if Bacon had approximated to this view of the nature of things, for in several passages he identifies forms with laws of activity. Thus, he says:

> When I speak of forms I mean nothing more than those laws and determinations of absolute actuality which govern and constitute any simple nature, as heat, light, weight, in every kind of matter and subject that is susceptible of them. Thus the form of heat or the form of light is the same thing as the law of heat or the law of light. . . . Matter rather than forms should be the object of our attention, its configurations and changes of configuration, and simple action, and law of action or motion; for forms are figments of the human mind, unless you call those laws of action forms. . . . Forms or true differences of things, which are in fact laws of pure act. . . . For though in nature nothing really exists besides individual bodies, performing pure individual acts according to a fixed law, yet in philosophy this very law, and the investigation, discovery and explanation of it, is the foundation as well of knowledge as of operation. And it is this law, with its clauses, that I mean when I speak of forms.

A study of the various passages in the *Novum organum* in which the definition of forms is attempted seems to show that Bacon's forms are no ideas or abstractions but highly general physical properties. Further, it is hinted that these general qualities may be looked upon as the modes of action of simple bodies. Thus, by a knowledge of forms, Bacon believed that man's practical control of nature would be enormously increased. For example, so long as we possess only certain practical recipes for the production of heat, these can be applied only when the requisite conditions are available. But, armed with the knowledge of what heat consists of (*i.e.,* the form of heat is violent, irregular, motion of particles), we can produce heat by any method which will induce such motion. This fruitful conception, however, Bacon does not work out; and though he uses the word cause and identifies form with formal cause, yet it is perfectly apparent that the modern notions of cause as dynamical and of nature as in a process of flow or development are foreign to him and that in his view nature was regarded in a purely statical aspect.

That the sciences are organically connected is a thought common to him and to his distinguished 13th-century predecessor, Roger Bacon. "I that hold it for a great impediment towards the advancement and further invention of knowledge, that particular arts and sciences have been disincorporated from general knowledge, do not understand one and the same thing which Cicero's discourse and the note and conceit of the Grecians in their word *circle learning* do intend. For I mean not that use which one science hath of another for ornament or help in practice; but I mean it directly of that use by way of supply of light and information, which the particulars and instances of one science do yield and present for the framing or correcting of the axioms of another science in their very truth and notion." In accordance with this, at the basis of all Bacon placed a body of general truth, common to all the sciences, which he called the *prima philosophia.* Following this summary philosophy come the sciences proper, rising like a pyramid in successive stages, the lowest stage being occupied by natural history or experience; the second by physics; the third, which is next the peak of unity, by metaphysics. The knowledge of the peak or of the one law which binds nature together is perhaps denied to man.

The Baconian Method.—Nature presented itself to Bacon's mind as a huge congeries of phenomena, the manifestations of some simple and primitive qualities, which were hidden from us by the complexity of things themselves. The world was a vast labyrinth, the clue to which, the *filum labyrinthi,* is the new method of induction. But the new method could not be applied until facts had been observed and collected. Concealed among the facts presented to sense are the causes or forms, and the problem therefore is so to analyze experience that we shall with certainty and mechanical ease arrive at a true conclusion. For this purpose Bacon proposed to draw up three "tables of comparative instances." We must have before us instances in which any given nature is present; instances in which it is absent; and instances in which the nature is present in different degrees. To make clear the nature of these tables let us take for example the case of heat. We wish to discover the form of heat; *i.e.,* the condition which is present or absent when heat is present or absent and which increases or decreases as heat increases or decreases. To do this we begin with a process of elimination of all those inessential conditions which are not found always and only in conjunction with the phenomenon of heat. Bacon, for instance, excludes the property of rarity, since metals such as gold are of very great density, even though heated. Thus, by a process of elimination, we should arrive at the true form of heat. But as it is exceedingly difficult to make our exclusive table at all exhaustive, Bacon proposes that we pause when a certain stage is reached and a tentative survey be made of the state of the inquiry. This survey, which he calls the "first vintage," is probably Bacon's nearest approximation to the modern conception of the formation of a scientific hypothesis, the department in which Bacon's chief weakness lay. It is evident that if the tables were complete and our notions of the respective phenomena clear the process of exclusion would lead infallibly to the detection of the cause or form. But it is just as evident that these conditions can never be fulfilled adequately. Such was the method devised by Bacon and to which he ascribed the qualities of absolute certainty and mechanical simplicity. But even supposing that this method were accurate and completely unfolded, it is evident that it could be made applicable and produce fruit only when the phenomena of the universe have been very completely tabulated and arranged.

Criticism of Bacon's Philosophy.—It has been pointed out, and with perfect justice, that science in its progress has not followed the Baconian method. The reason of this is not far to seek. The process of scientific discovery is essentially an act of judgment. Facts, phenomena, are infinite in number. We cannot choose them all, as Bacon would have had us do, and then pass them through a mill of logic and elicit a result. Still less dare we choose at random. The process of choosing facts is an act of judgment on the part of the man of science. His choice is doubtless limited by his knowledge of his art. He exercises his judgment to choose things which bear a certain relation to each other. But no knowledge of the nature of reasoning, however profound, nor even knowledge of his science, however complete, will make a man a scientific discoverer. The scientific man has, in fact, to practise two distinct mental processes, the making of the discovery and the demonstration of its truth. Essentially the two processes are distinct and the one might be largely developed while the other was in a state of relative arrest.

This distinction between the act and demonstration of discovery was consistently missed during the middle ages. Medieval thought is further distinguished from our own by the persistent conviction in those ages that a wide measure of truth could be

elicited from a very small series of observations by the extensive use of ratiocination. The latter error Bacon clearly discerned, and his discernment entitles him to rank as the herald of modern science. His claim that a direct appeal to nature was the only way to truth at once raised the functions of the observer while it tended to depress the vast medieval claims for ratiocination.

On the other point in which our thought is separated from that of the middle ages, however, Bacon remained in darkness. He succeeded indeed in emphasizing the importance of the operation of collection of facts, but he failed to perceive how deeply the act of judgment must be involved in the effective collection of facts.

Bacon's Influence.—It is significant that Bacon has made himself more felt in the department of the moral and metaphysical sciences than in the physical. While many who have written about science have done him homage—notably Voltaire and Jean le Rond d'Alembert and the other contributors to the *Encyclopédie* by whom he was regarded as "the greatest, the most universal and the most eloquent of the philosophers"—while men of science such as Gottfried Leibniz, Christiaan Huygens and, above all, Robert Boyle have had him in good regard, yet there is not the least evidence that these or any other eminent scientific men have ever followed his method. Despite Bacon's failure in the field of the practical application of his method, however, the world certainly owes to him some developments of high importance, which may be summarized as follows:

1. He did in fact set forth clearly the widening intellectual breach which separated the men of his day from the middle ages. He perceived the defects of the scholastic method, and in the clearness of his vision and explanation he stands above his contemporaries, men such as Tommaso Campanella (*q.v.*) (1568–1639) and Giordano Bruno (*q.v.*) (*c.* 1548–1600), who like him were striving toward a new form of intellectual activity.

2. English writers of the later 17th century concur in ascribing to the impetus of Bacon's writings the foundation of the Royal society (*q.v.*). It is one of the ironies of history, however, that Bacon himself was not associated with two of his English contemporaries who were notable exponents of the experimental method—William Gilbert and William Harvey (*qq.v.*).

3. It is perhaps in the department of psychological speculation that the influence of Bacon has been most marked. The basic principle of John Locke's work, *An Essay Concerning Humane Understanding* (1690), that all ideas are the product of sensation and of reflection is implicit in the first aphorism of Bacon's *Novum organum*, "Man, who is the servant and interpreter of nature, can act and understand no further than he has observed, either in operation or in contemplation, of the method and order of nature." The whole atmosphere of Locke's work is taken from or at least is characteristic of the *Novum organum*. Through the practical tendency of his philosophy and through Locke, Bacon was the father alike of English psychological speculation and of the empirical method in the department of ethics. Whatever his positive achievements may have been we may thus accord to him his own claim that he "rang the bell which called the wits together."

(C. St.; R. A.; J. M. M.; X.)

Literary Importance.—The most notable of Bacon's literary works are the *History of Henry VII*, the *Essays* and the *New Atlantis:* these stand out from among a number of eulogies, apothegms, paradoxes, speeches for masques, sacred meditations, collects, versified psalms and a few ascribed lyrics, by virtue of the interesting matter and equally for their dense and pungent style.

Bacon had large plans for a history of Britain but he had much else on hand and completed only the brilliant study of Henry VII. The diplomatic Tudors were congenial; in this history Bacon's wit is sharp in narrative and characterization. In the Utopian fiction there is a more leisurely eloquence. The *Essays*, which he associates with Seneca's *Epistles*, were ostensibly the most informal of his compositions but they have stood time's testing even better than the lucid, dignified *Advancement of Learning* which is finer in construction. The *Essays* are good value at any time but come best as an index to the volume of his total reflections. Edward Arber's *Harmony of the Essays* (1871) collects the three editions (10 essays in 1597; 38 in 1612; and 58 in 1625) and reveals Bacon at work. Similar exercises in addition and revising may be observed in his philosophical works. His secretary claims to have seen about 12 versions of *De augmentis* and comments "he did rather drive at a masculine and clear expression than at any fineness or affectation of phrases . . . if his style were polite, it was because he would do no otherwise."

Bacon made rhetorical collections in the *Promus of formularies and elegances* and the *Colours of Good and Evil* but it is misleading to confine attention to works deemed literary in any narrow sense. In *De augmentis VIII* he remarks that he was born "for letters," a claim as true as it is unusual. In the last analysis it is by force of style that he transmutes literature "of knowledge" into literature "of power." He admitted to lighting his torch at other men's candles; he left much unfinished; he lies open to the criticism of specialists on all sides, but among those who have used language reliably, forcibly and subtly he is unassailable. Yet it is not wise to approach him as a pure stylist; his is an applied art. He is always busy about some observation, reflection or argument and it is to this that his readers must first attend. The reward is to find delight stealing in by the stimulus of his images, the finely fashioned epigrams, the poised phrases, the elaborate build of his paragraphs and the accomplished varying of tone. He was distrustful of the imagination and would keep it to subserve the reason; the result is a display of rhetorical power such as his own theory of that art would have recognized and approved. He was alive to the dangers of language and yet fascinated by it. It is legitimate to infer that what his practice at the bar, in parliament and at court had taught him of the "points and stings" of words is reflected in the nicety and savour of those remarks in the *Essays* which have been quoted until they rank as proverbs. Bacon was interested in problems of communication and although he deplored the contemporary excesses in the cult of "choiceness of the phrase, and the round and clean composition of the sentence, and the sweet falling of clauses and the varying . . . with tropes and figures" it was his achievement to recover the balance of sense and sound without loss of these very graces. Jonson praised his oratory: "No man ever spoke more neatly, more pressly, more weightily . . . the fear of every man that heard him was, lest he should make an end."

This judgment is based on Bacon's use of English but he was bilingual and many characteristics could be illustrated as well from what he close to publish in Latin, as for instance, in the *De sapientia veterum*, a work worth more respect than it commonly receives. C. W. Lemmi has done it a service by relating it to the tradition of myth interpretation to which it belongs (*The Classic Deities in Bacon*, 1933).

Bacon was reserved by temperament, by necessity of high office and by genius and he is notoriously hard to know. He is never intimate except in an occasional letter, but he is not in an absolute sense inaccessible. It is his style that betrays his tastes, his biblical education, his sensuous alertness and above all reveals a mind continually "musing, searching, revolving new notions and ideas." To read him is "to be moved with a desire to know" and it is palpable from the preface to his *Pseudodoxia epidemica* that Sir Thomas Browne was stirred to follow him in investigating vulgar errors, for all that the follower's method and result differ so widely from his master's. Sir Henry Wotton, as provost of Eton, recommended Bacon to be read "in my domestic college as an ancient author." How he has fared in the modern world is usefully indicated by A. E. Taylor (1926) and by Rudolf Metz in "Bacon's part in the Intellectual Movement of his time," in *Seventeenth-Century Studies Presented to Sir Herbert Grierson* (1938). Perhaps all that Bacon himself would ask is still to be "weighed and considered."

BIBLIOGRAPHY.—*Editions:* The great modern edition is that of J. Spedding, R. L. Ellis and D. D. Heath, 7 vol. (1857–59). A further 7 vol. (1861–74) by Spedding, *The Letters and Life* . . . include also

the occasional writings. There is a useful 1-vol. selection, by J. M. Robertson, mainly of the philosophical works (1905), containing a summary of the problems of Bacon's life and thought. Numerous cheap editions and selections include that in the "World's Classics Series" (1901; new ed. 1937) and *English Works of Francis Bacon*, ed. by Sidney Lee (1905). Of countless editions of the *Essays* those by the following are the most useful: W. A. Wright (1862); E. A. Abbot, 2 vol. (1876); S. H. Reynolds (1890); M. A. Scott (1918); R. Wilson (1924); E. Arber, *Harmony of the Essays* (1871). *The Advancement of Learning* has been ed. by W. A. Wright, 5th ed. (1900); F. G. Selby, 2 vol. (1892–95); with the *New Atlantis*, "World Classics Series," by T. Case (1906); with the *Essays* and *Colours of Good and Evil* (1920). The *New Atlantis* was ed. by A. B. Gough (1915); and with Sir Thomas More's *Utopia* by H. Gotein (1925). The *Novum organum* was ed. by T. Fowler, 2nd rev. ed. (1889). *Essays, Advancement of Learning, New Atlantis* and other pieces were ed. by R. F. Jones (1937). *The Great Instauration: Proemium, Preface, Plan of the Work and Novum organum* was ed. by G. Kennedy (1937).

Life and Thought: T. Fowler, *Francis Bacon*, in the "English Philosophers Series" (1881); R. W. Church, *Francis Bacon*, "English Men of Letters Series" (1884); J. Nichol, *Francis Bacon, His Life and Philosophy* (1888–89); K. Fischer, *Franz Bacon von Verulam* (1856; Eng. trans., 1857), *Franz Bacon und seine Nachfolger* (1875); C. de Rémusat, *Bacon: sa vie . . . et son influence* (1857); A. Casson, *Über Bacon von Verulams wissenschaftliche Prinzipien* (1860); J. von Liebig, *Über Francis Bacon von Verulam und die Methode der Naturforschung* (1863); B. Tillotson, "Words for Princes," *Essays in Criticism and Research* (1942); K. R. Wallace, *Francis Bacon on Communication and Rhetoric* (1943). (C. Sr.; R. A.; J. M. M.; X.)

BACON, HENRY (1866–1924), U.S. architect whose work represents the classical revival styles of the late 19th and early 20th centuries, was born at Watseka, Ill., Nov. 28, 1866. He studied architecture at the University of Illinois and then joined the firm of McKim, Mead and White in New York city. Later he was a member of the firm of Brite and Bacon and after that worked independently. He successfully executed numerous commissions ranging from banks to bridges but came to specialize in public monuments and memorials. In 1911 he received his most important commission, the Lincoln memorial in Washington, D.C., now a major landmark of the capital city. He died Feb. 16, 1924, in New York.

See C. A. Platt's tribute to Bacon in R. U. Johnson *et al.* (eds.), *Commemorative Tributes to Page, Wilson, Bacon* (1925). (C. J. W.)

BACON, JOHN (1740–1799), British sculptor, was born in Southwark on Nov. 24, 1740, and apprenticed at 14 in a porcelain works at Lambeth. There he was at first employed in painting small ornamental pieces of china, but soon became modeler to the works. During his apprenticeship he improved the method of working statues in artificial stone, an art which he afterward carried to perfection. Bacon first attempted working in marble about 1763, and improved the method of transferring the form of the model to the marble (technically "getting out the points") by the invention of a more perfect instrument for the purpose. This instrument was more exact, took a correct measurement in every direction, was contained in a small compass and could be used upon either the model or the marble. In 1769 he won the first gold medal for sculpture given by the Royal Academy, his work being a bas-relief representing the escape of Aeneas from Troy. In 1770 he exhibited a figure of Mars, which gained him the gold medal of the Society of Arts and his election as associate of the Royal Academy. He was then engaged to execute a bust of George III, intended for Christ Church, Oxford. He died on Aug. 4, 1799. Perhaps his best works are to be found among the monuments in Westminster abbey.

BACON, LEONARD (1802–1881), U.S. Congregational preacher, church historian and writer, sometimes referred to as the "Congregational pope" of New England, was born at Detroit, Mich., on Feb. 19, 1802, the son of David Bacon (1771–1817), missionary among the Indians in Michigan. The son graduated at Yale in 1820 and at the Andover Theological seminary in 1823, and from 1825 until his death was minister in the First church (Congregational) in New Haven, Conn., although he gave up the active pastorate in 1866. He was, from 1826 to 1838, an editor of the *Christian Spectator;* was one of the founders of the *New Englander* (later the *Yale Review*), and, with R. S. Storrs, H. C. Bowen and others, of the *Independent* (1848). He served as acting professor of didactic theology at Yale university from 1866 to 1871 and as lecturer on church polity and U.S. church history from 1871 until his death.

An advocate of liberal orthodoxy himself, in all the heated theological controversies of the day Bacon used his influence to bring about harmony, and in the councils of the Congregational churches he manifested great ability both as a debater and as a parliamentarian. He also was identified with the temperance and antislavery movements, in which, as in most other controversies, he took a moderate course. His *Slavery Discussed in Occasional Essays From 1833 to 1846* (1846) exercised considerable influence upon Abraham Lincoln. The most important of his historical works is his *Genesis of the New England Churches* (1874). Bacon died on Dec. 24, 1881.

See the commemorative volume issued by his congregation (1882) and Williston Walker's *Ten New England Leaders* (1901).

(W. W.; X.)

BACON, NATHANIEL (1647–1676), Virginia planter and leader of "Bacon's rebellion" in 1676, was born in Suffolk, Eng., a kinsman of the famous Francis Bacon (*q.v.*). He graduated from Cambridge, toured the continent and studied law at Gray's Inn. Until shortly before his arrival in Virginia in 1674, Bacon was destined to the life of a country squire. His marriage to Elizabeth, daughter of Sir Edward Duke of Suffolk, was violently opposed by her father. Her disinheritance and the involvement of Bacon in a rather unsavory deal to defraud a neighbour of his inheritance contributed to Bacon's decision to migrate to America.

Adequately financed by his father, Bacon acquired two estates along the James river—a main plantation 40 mi. above Jamestown and an outer plantation at the present site of Richmond. By virtue of his social position and financial means, his kinship by marriage to Gov. William Berkeley, and the wealth and influence of his cousin, Nathaniel Bacon, Sr., he was appointed to the governor's council in less than one year after his arrival in Virginia.

The cordiality between Governor Berkeley and Bacon was short-lived. In part the differences seem to have been a result of personality conflicts between two ambitious and strong-minded men —an irascible, opinionated, aging, cautious and avaricious governor and his youthful, ambitious, impetuous and demagogic cousin. The initial dispute arose over the Indian policy espoused by Berkeley. Bacon endorsed a policy of removing all Indians in the interests of unlimited territorial expansion and as a revenge for Indian attacks on the frontier settlements. Berkeley, influenced by fear of a general Indian war, a sense of justice, a concern for the Indian trade and a desire to avoid the costs of a major conflict, advocated a policy of caution.

In defiance of Berkeley, Bacon organized an expedition against the Indians. At the start the governor branded Bacon a rebel but was soon forced by public pressure to give Bacon a commission. Later he again denounced Bacon's activities as rebellious and the latter turned his forces on Berkeley and for a time controlled practically all of Virginia.

At the height of his power Bacon died and the rebellion collapsed. Because he exploited the colonial grievances which stemmed in part from the arbitrary, self-perpetuating and privilege-seeking nature of Berkeley's government, Bacon often has been pictured as a democratic reformer and forerunner of the American Revolution, but many historians reject this interpretation.

See T. J. Wertenbaker, *Torchbearer of the Revolution* (1940) and W. E. Washburn, *The Governor and the Rebel* (1957). (Ra. Mu.)

BACON, SIR NICHOLAS (1509–1579), lord keeper of the great seal of England during the reign of Elizabeth I, was born at Chislehurst, Kent, the second son of Robert Bacon of Drinkstone, Suffolk. He was educated at Corpus Christi college, Cambridge. After spending some years in Paris, Bacon returned to England, entered Gray's Inn, and was called to the bar in 1533. He became a bencher of Gray's Inn in 1550 and treasurer two years later. He was appointed solicitor of the court of augmentations in 1537 and was made attorney of the court of wards and liveries in 1546. Despite his known Protestant sympathies he retained this office throughout the reign of Mary I, but he was forbidden to leave England.

The accession of Elizabeth I in Nov. 1558 brought Bacon immediately to prominence. He became a privy councilor, was knighted, and as lord keeper took custody of the great seal on Dec. 22. In April 1559 he was authorized to exercise the full jurisdiction of lord chancellor. Bacon was dismissed from court in 1564 when John Hales, of whom he was patron, displeased the queen by writing a pamphlet suggesting Lady Catherine Grey as Elizabeth's heir. But Bacon soon proved his innocence and regained his influence, later himself writing a reply to Sir Anthony Browne, another supporter of the house of Suffolk to which Lady Catherine belonged.

Bacon was a close friend of Sir William Cecil, afterward Lord Burghley, and of Matthew Parker, archbishop of Canterbury, and with them he did much to establish and maintain the Elizabethan church settlement. The conference between the Protestant and Catholic parties over which he presided in March 1559 weakened the power of the Catholics. He urged on the queen an alliance in 1561 with Navarre and the French Protestants; in the same year, he and Cecil persuaded her to refuse the pope's invitation to send representatives to the third assembly of the Council of Trent. He thoroughly distrusted Mary Stuart and he warned Elizabeth against the proposal made in 1569 to marry her to the duke of Norfolk and against plans for her restoration in 1570.

Bacon died in London on Feb. 20, 1579. He had been twice married and by his first wife Jane had three sons and three daughters. His eldest son, Nicholas, was in 1611 created premier baronet of England by James I. His sons by his second wife, Ann, were Anthony, a diplomatist, and the illustrious Francis Bacon.

BACON, ROGER (*c.* 1220–*c.* 1292), English philosopher, scientist and educational reformer, belonged to a wealthy family which fought on the king's side in the Barons' War. The place of his birth is uncertain; one tradition assigns it to Ilchester in Somerset, another to the parish of Bisley in Gloucester. The approximate date of his birth is deduced from his having stated in 1267 that it was 40 years since he first learned the alphabet. He was well versed in the classics and enjoyed the advantages of an early training in the various disciplines of the quadrivium (geometry, arithmetic, music and astronomy); and he boasts that he had frequently "heard" and "read" the works of Aristotle. As he lectured in the faculty of arts at Paris, it seems probable that his degree of master of arts was conferred there (presumably not before 1241). He relates that he saw Alexander of Hales with his own eyes and that he heard William of Auvergne dispute twice in the presence of the whole university; Alexander died in 1245 and William in 1249.

About 1247 a considerable change took place in Bacon's intellectual development. The work to which he devoted time, energy and money from that date forward marked a definite departure from the usual routine of the faculty of arts. He expended huge sums of money in experimental research, in acquiring "secret" books, in the construction of instruments and of tables, in the training of assistants, in seeking the friendship of savants. No traces of such preoccupations appear in the earlier part of his career when he lectured on Aristotelian and pseudo-Aristotelian treatises at the University of Paris. The change was caused by his return to Oxford and the influence of the great Robert Grosseteste, of Adam de Marisco and of Thomas the Welshman. From 1247 to 1257 Bacon devoted himself wholeheartedly to the cultivation of those new branches of learning to which he was introduced at Oxford—languages, mathematics, optics, alchemy and astronomy. He complacently remarks that the prodigious energy and zeal that he displayed in the pursuit of experimental science was talked about everywhere.

In 1257 another marked change took place. Bacon speaks of himself as forgotten by all and, as it were, buried. The reasons for this were ill-health and his entry into the Order of Friars Minor. His university career and his literary career seemed to be at an end. There can be no doubt that his feverish activity, his amazing credulity, his superstition and his contempt for those not sharing his interests—a contempt which he voiced at every opportunity—incurred the displeasure of his superiors and brought him under some severe form of discipline. He decided to appeal to Pope Clement IV, whom he had known when the latter was in the service of the Capetians. In a letter written from Viterbo and dated June 22, 1266, the pope referred to letters received from Bacon who had come forward with certain proposals of great importance for the welfare of the church and of the universities. The pope desired to be more fully informed of these projects and commanded Bacon to send him the work that he had already tried to obtain before his elevation to the papacy. But Bacon had had in mind a vast encyclopaedia of all the known sciences, which required many collaborators and could be undertaken only if the pope were to set up some institute where savants might dispose of the means and funds necessary. The work, then, was merely projected when the pope thought that it already existed. But in obedience to the pope's command Bacon set to work and in a remarkably short time had dispatched the *Opus majus*, the *Opus minus* and the *Opus tertium*—in that order. He had to do this secretly and notwithstanding any command of his superiors to the contrary; and even when the irregularity of his conduct attracted their attention and the terrible weapons of spiritual coercion were brought to bear on him he was deterred from explaining his position by the command of secrecy enjoined on him by the pope. In the circumstances his achievement was truly astounding. He did not fail to remind the pope that he could have covered quires of vellum with the "puerilities" and vain speculations which filled the commentaries and *summae* of the leaders of the schools. He aspired to penetrate realms undreamed of in the schools at Paris and to lay bare the secrets of nature by positive study. His cherished sciences were languages, mathematics, optics, alchemy and astronomy, and his originality lies not so much in any positive contribution to the sum of knowledge as in his insistence on fruitful lines of research and methods of experimental study. The *Opus majus* was a *persuasio*, an effort to persuade the pope of the urgent necessity and manifold utility of the reforms he proposed. The death of Clement IV in Nov. 1268 brought to an end Bacon's dreams of gaining for the sciences their rightful place in the curriculum of university studies.

Bacon projected yet another encyclopaedia of which only fragments were ever published, viz., the *Communia naturalium* and the *Communia mathematica*, written about 1268. In 1272 there appeared the *Compendium philosophiae*. In philosophy—and even Bacon's so-called scientific works contain lengthy philosophical digressions—he is the disciple of Aristotle and not of St. Augustine or of Avicenna. Even though he does incorporate Neoplatonist elements into his system of philosophy, this remains, nevertheless, Aristotelian in its main lines.

Some time between 1277 and 1279 Bacon was condemned to prison by his fellow Franciscans because of certain suspected novelties in his teaching. The condemnation was probably because of his bitter attacks on the theologians and scholars of his day and his excessive credulity in matters of alchemy and astrology. How long he was imprisoned it is not possible to determine. His last work, incomplete as so many others, was written in 1292 and shows him as aggressive as ever. The tradition that he died in 1292 and was buried in the Franciscan church at Oxford is related by John Rous. Exaggerated accounts of his wonderful experiments won him a place in popular literature and doubtless played some part in determining the title *doctor admirabilis* under which he became known to posterity. *See* also Index references under "Bacon, Roger" in the Index volume.

ography of Bacon's works) (1914); Theodore Crowley, *Roger Bacon, the Problem of the Soul in His Philosophical Commentaries* (1950); S. C. Easton, *Roger Bacon and His Search for a Universal Science* (1952); A. C. Crombie, *Robert Grosseteste and the Origins of Experimental Science, 1100–1700* (1953). (T. Cy.)

BACON is the cured side of a pork carcass, but varying in type in the United States and Europe. It has been one of mankind's favourite meats throughout recorded history because of its comparative ease in smoke-curing and its keeping qualities. As "the poor man's meat" of medieval Europe it was the subject of famous folk sayings. Rabelais, writing in Paris in the 1540s, used the phrase, "Let us flee and save our bacon." The saying, "Bring home the bacon," still a simile for material success, reputedly originated at the monastery of Dunmow in Norman England where the monks gave a flitch of bacon to any man who knelt before the church door and swore that "for twelve months and a day, I have never had a household brawl nor wished myself unmarried."

Migrating to the new world with the first Spanish, French and English settlers, bacon continued its ancient role. It was such a necessity in colonial New England that Puritan authorities disregarded its prevalence in the homes of widows and orphans seeking public charity. Consequently, it became a standard ingredient of the most famous New England dishes.

The dietary importance of the breakfast meal emphasized by medical researchers in the 20th century again validated broiled or fried bacon strips as a mainstay of the American's breakfast menu. Bacon chunks persisted, too, as popular "flavouring" for green beans, squash, turnip greens and other fresh vegetable cookery in the southern United States. Bacon fats and chunks remained ingredients of most fish, dried bean, fried potato and corn meal dishes throughout the United States.

In the second half of the 20th century the leading bacon producing and exporting countries were the United States, Denmark, Canada, the Netherlands, Ireland, Poland and Sweden. The United Kingdom, Germany, France and Austria were large importers.

Types.—Bacon in the United States generally refers to the fatty side between the fourth or fifth rib and the hipbone. The bacon represents about 12% of the live weight of a pig. After the spareribs are removed, the cut is trimmed to a rectangular shape. With the choice grades of bacon, all "seeds" or mammary tissue and rib cartilages or "buttons" are removed. From the front of the bacon, a strip from 1½ to 2 in. wide is removed. This may be cured and smoked as a seasoning piece and is designated a bacon brisket. The jowl is occasionally trimmed square, cured and smoked, after which it is known as a bacon square.

Canadian bacon is the cured and smoked fleshy part of a heavy pork loin (weighing more than 14 lb.). The tenderloin and all the bones are removed. The lean strip is cured and smoked.

In Europe, and particularly in Great Britain, the term bacon generally designates a Wiltshire side—one-half of a properly finished bacon-type pig that weighed from 150 to 210 lb. alive. For the British market, supplied by home and continental European producers, carcasses are centre split and the neck and shanks trimmed closely. Their length is graded according to the varying requirements of the ministry of agriculture, the topmost grade, AA+, having in 1960 a minimum length of 800 mm. from the indentation of the first rib to the anterior edge of the aitchbone. The tenderloin, backbone, pelvic bone and breastbone are removed and the entire side mildly cured and lightly smoked. Wiltshire sides weighing 50 to 65 lb. are preferred. Wiltshire sides are generally graded according to the following maximum measurements, (in millimetres) of thickness of back fat for each of grades 1, 2 and 3:

Grades	Shoulder	Mid-back	Loin
1	50 mm.	30 mm.	30 mm.
2	55 mm.	35 mm.	35 mm.
3	60 mm.	40 mm.	40 mm.

Quality.—Although there is a distinct preference on the part of consumers for the leaner grades of bacon, quality bacon must contain some fat. Too much fat results in a wasty bacon and too little in a flabby bacon lacking in tenderness. Choice bacon should have a good lean streak, and the side should be uniform in thickness. A choice breakfast bacon usually is trimmed so that the length is approximately two and one-half times the width. The fat should be firm, white and flaky. A rubbery condition of the fat generally indicates a lack of tenderness. A thin rind, free from wrinkles, is considered to be an indication of quality.

Curing.—Bacon is cured by the application of salt, sugar and sodium or potassium nitrate or sodium or potassium nitrite. Salt serves as a preservative and flavouring agent; sugar reduces the harshness of the salt and under favourable conditions may promote the growth of useful bacteria. Cane sugar is commonly used because dextrose (corn sugar) will cause excessive browning upon frying. Sodium or potassium nitrate, reduced to nitrite by bacterial action, reacts with the meat pigment myoglobin to form the cured meat colour. Potassium and sodium nitrite also act as bacteriostatic agents.

Two basic types of curing are employed. Bacon cured on the farm or in small plants serving a local trade is more strongly cured than most commercial products. In the farm curing operation either a dry cure or a brine cure is used. For dry curing, 6–6.5 lb. of a mixture of 8 lb. of salt, 2 lb. of sugar and 2 oz. of sodium nitrate are applied to each 100 lb. of meat. This is spread over the fresh pork as it is packed, usually in wooden boxes. Dry cured bacon is cured for approximately two days per pound depending upon the thickness (10-lb. cuts will be cured 20 days) at 38° F. One or more times during the cure, the position of the bellies is changed to achieve a more uniform cure, an action called overhauling. Curing also may be done in a water solution of the dry cure ingredients. The bellies are packed in tierces or barrels and pickle poured over them. After the curing, the bellies are rinsed with water to remove the excess cure from the surface and are placed on hangers for smoking.

A rather heavy smoke is applied to country cured bacon. Hardwood sawdust generally is preferred. The smoking process results in some loss of moisture, tends to seal the surface and deposits a layer of smoke constituents that have a mild bacteriostatic effect. This type of bacon frequently is sold in complete sides or slabs but may be sliced at the point of purchase.

Most commercially cured bacon is much milder than that referred to above. In the second half of the 20th century emphasis has been placed upon curing procedures. It is not uncommon for bacon to be sold in the retail store six or seven days after the slaughter of the hog. Accelerated curing procedures rely on rapid and thorough penetration of the cure by pumping. One piece of equipment for this purpose has 144 hollow needles, which penetrate the entire belly at close intervals. The cure for such bacon is made from a 60° to 70° brine to which is added 25 to 100 lb. of sugar and up to 1½ lb. of sodium or potassium nitrite or their equivalent of nitrate per 100 gal. of brine. The bellies are pumped to approximately 110% of their "green" weight. Most of this increase in weight is lost during subsequent processing. The pumped bellies are frequently piled on skids or pallets and cured a few days. The trend in the second half of the 20th century was toward smoking immediately after pumping. Heat processing and smoking is completed in 12 to 15 hours with an internal temperature of 120° to 125° F.

The addition of ascorbic acid to the curing brine accelerates the curing process, tends to retain colour by retarding oxidation and permits heat processing to take place immediately after pumping. Alkaline phosphates have been used to decrease the amount of shrinkage in smoked products but their use has not proved to be so helpful in bacon as in other cured products. Artificial sweeteners, such as sodium cyclamate, also are used as a replacement for sugar. The use of these eliminates the undue darkening of bacon cured with dextrose sugars. Attempts have been made to accelerate the deposition of smoke by an electrostatic process in which bacon can be smoked in 30 minutes and the smoke particles are attracted to the bacon.

While bacon keeps better than fresh pork, the mildly cured products are perishable and must be refrigerated. Sliced bacon is more perishable than slab bacon, and extreme care is needed in slicing and packaging to keep it fresh.

Food Value.—Bacon's chief food value is in its high caloric content: a pound of bacon contains about 3,000 cal. Crisp bacon has a lower energy value than bacon less well cooked. The fat is completely digested. The protein in bacon is of high quality and readily digested. The leaner grades especially of Canadian bacon have a materially higher protein value. *See* also PORK; HAM.

(W. J. L.; G. D. W.; R. W. HD.)

BACONIAN METHOD is the method of interpreting nature (or studying natural phenomena) formulated by Francis Bacon (*q.v.*). It was intended to replace the method of citing the views of authorities or of having recourse to fanciful guesses. It insisted on the dismissal of prejudices and preconceptions of all kinds and on the close and methodical observation of the facts concerned. It was essentially an empirical method and consisted of three main steps: first comes a description of the facts; next, a tabulation or classification of them into three classes showing (1) instances of the presence of the characteristic or quality, etc., under investigation, (2) instances of its absence and (3) instances of its presence in varying degrees; thirdly, the rejection or elimination of whatever appears, in the light of these tables, not to be connected with the phenomenon under investigation and the determination of what is connected with it. Bacon may be credited with recognizing, in their essence, the methods of agreement, the joint method and the method of concomitant variations. But he exaggerated the mechanical element in scientific investigation when he assumed that by following his method anybody might make sound scientific discoveries, much in the same way as anybody might, with the help of a pair of compasses, construct an almost perfect circle. *See* also INDUCTION; SCIENTIFIC METHOD.

BACONTHORPE, JOHN (JOHANNES BACONTHORP or BACON) (d. 1348?), English theologian and philosopher, known by the honorific of *Doctor resolutus*, was born at Baconthorpe in Norfolk and brought up in the Carmelite monastery of Blakeney. He studied in Paris, taught at Cambridge and perhaps at Oxford and was provincial of the English Carmelites from 1327 to 1333. A learned and sharp critic of such theologians as Thomas Aquinas, John Duns Scotus and Henry of Ghent, he failed to counter them with constructive work. His deep knowledge of Averroës (*q.v.*) and his benevolent interpretation of some of his views, although he dissented on fundamentals, availed him the title of *princeps Averroistarum*. He wrote a commentary on Peter Lombard's *Sentences* (first published in Paris, 1484); *Quodlibeta* (first published in Venice, 1527); commentaries on St. Matthew, St. Paul's Epistles and on some works of St. Augustine and of St. Anselm.

(L. M.-Po.)

BACTERIA, microscopic organisms whose influence in the biosphere is incalculable. They include far more beneficial types than spoilers and pathogens. *See* BACTERIOLOGY; BACTERIAL AND INFECTIOUS DISEASES.

BACTERIAL AND INFECTIOUS DISEASES. An infectious disease can be defined in the broadest sense as a disease that may be transmitted from one living thing to another; but it is probably better to use an etiological definition and to say that it is one that is caused by invasion of the host by a microorganism capable of multiplying in the tissues, of giving rise to pathological lesions and of being passed on to other hosts of the same or a different species. The host may be a man, an animal, a plant, an insect or perhaps even a microorganism itself, such as the infection of bacteria with the viruslike particles known as bacteriophages. The microorganism must be able to reproduce itself in the tissues of the host and to give rise to cellular damage. Mere implantation of the microorganism on the surface membranes—skin, conjunctiva, mucosae—accompanied by its reproduction is not sufficient to constitute disease, since many bacteria find their normal habitat in these situations and flourish without harming the host. This is an example of parasitism, but not of infection in the strict sense of the word. The term infectious implies that the disease can be passed from one host to another. A disease caused by a microorganism that is unable to set up a similar disease in other suitable hosts to which it is transmitted is better described as an infective disease. The distinction between the two is not always easy to draw but is worth maintaining. Lastly, it may be pointed out that the use of the word infection in this article is restricted to invasion with unicellular microorganisms. Invasion by multicellular organisms, such as worms or insects, is considered under PARASITOLOGY. This article, dealing with infection in a broad sense, including both infectious and infective diseases contains the following sections:

I. GENERAL BACKGROUND

1. Origination of Infectious Disease.—There is no exact knowledge of when or how infectious disease originated. Microbiology is a science of such recent development that any explanation of the way in which bacteria and other infective microorganisms arose during the process of evolution and became adapted to growth in the tissues of more highly organized living beings must be a matter for mere speculation. It is fairly safe to surmise that bacteria developed first of all as saprophytes, obtaining their food material from nonliving matter. From time to time some of these organisms, which were probably widespread in soil and decaying vegetable material, must have gained access through wounds to the tissues of animals. Most of these organisms probably died off, either because they were not equipped with the necessary range of enzymes to obtain nourishment from the tissue fluids, or because they were killed by cellular or humoral activity on the part of the host. A few, however, may have succeeded in establishing themselves within the body. Since bacteria readily undergo variation, there must have been in these circumstances a natural selection of the variant that was most fitted to survive under the new conditions. To do this it must have been capable of inflicting serious damage on the host, usually by the production of some toxic substance, with the result that the host must often have succumbed to the attack. From a biological point of view, such an event is an unfortunate result for the microorganism; unless it can gain access to the body of another host, it will die out, and the particular variant, therefore, that has become adapted to a parasitic mode of life will perish. This probably happened over and over again, and many strains of potentially pathogenic organisms must have been evolved, have thrived for a brief period and passed into oblivion without leaving progeny to continue their race. Until a means could be found for fairly rapid transmission of the microorganism from one host to another, little progress would be possible in the development of pathogenic (disease-producing) organisms. F. M. Burnet is probably right in supposing that infectious disease must have developed among gregarious animals, and that it was therefore not till a fairly advanced stage in the evolution of life upon this globe that bacterial infection can have played any considerable part in the causation of disease.

Numerous species of microorganisms are known to exist, each of which is able to give rise to a specific disease. Since, however, the number of ways in which the body can react to microbial attack is limited, it follows that the final diagnosis of any disease is dependent upon laboratory investigation. For this reason many diseases that now are known to be distinct were confused with each other in the prebacteriological era. Influenza (*q.v.*), for example, is still imperfectly differentiated; it is difficult to say how many of the numerous epidemics that were described in the past by this name were in fact caused by the influenza group of viruses. Leprosy (*q.v.*) is another example. Readers of the Bible are well aware of the frequency with which this disease is men-

tioned. It is probable that the word leprosy was used to cover not only the disease caused by the bacillus *Mycobacterium leprae*, but also numerous other diseases giving rise to changes in the skin and subcutaneous tissues. The "leprosy," for instance, from which Naaman the Syrian suffered (II Kings v) and which was cured by bathing in the waters of the Jordan may well have been a form of psoriasis or other skin disease curable by sulfur. Plague (*q.v.*) is a name that was used in relation to several major outbreaks of disease. There is a fairly clear reference to it in the Old Testament (I Sam. v, vi); and there is little doubt that the plague of Justinian's reign in the 6th century, the Black Death of the 14th century and the Great Plague of London in 1665 were all caused by the true plague bacillus, *Pasteurella pestis*. The nature, however, of other plagues, described in Greece and the Roman empire, is more doubtful. Among diseases, apart from those just mentioned, that existed in the pre-Christian era are nonpulmonary tuberculosis, which has been recognized in Egyptian mummies; smallpox, which also probably occurred in ancient Egypt; and diphtheria, pneumonia and cholera, all of which appear to have been prevalent in Greek or earlier civilizations.

2. Historical Summary.—It would not be profitable in this article to describe in detail the various explanations that have been put forward during the centuries of the nature and causation of infectious disease. None of them, so far as can be judged, had any serious influence in guiding later investigators to the real truth, and their appeal is mainly to the historian. However closely the views of Hieronymus Fracastorius, Marcus Antonius von Plenciz and others approached the correct explanation, they were incapable of proof, at the time they were put forward, through lack of the necessary equipment and methods of study. Not until the development of the microscope by Anthony van Leeuwenhoek in the 17th century did it become possible to demonstrate the existence of living unicellular organisms by actual observation. Even then no immediate progress was made, because other techniques that were necessary to this end had not yet been developed.

Louis Pasteur (1822–95) was the real founder of microbiology. Becoming interested, as a chemist, in the problems of fermentation, he observed that there was a close association between the breakdown of certain organic compounds and the presence of living microorganisms, demonstrable by microscopic means. He made the further observation that apparently different microorganisms were associated with different types of fermentation, each type of organism being in this respect specific. These findings led him to challenge the widely held views of the German chemist Justus von Liebig (1803–73) and to face the still more fundamental problem of spontaneous generation. By a series of ingeniously devised experiments, Pasteur was able to bring convincing evidence to show that the multiple animalcules of Leeuwenhoek arose not from nonliving matter but from the reproduction of similar pre-existing animalcules. By growth in fluid media generation after generation of specific microorganisms could be cultivated, provided the necessary conditions, which he defined, were present. Media in which all living matter had been destroyed by heat remained permanently sterile, so long as the entrance of living cells was adequately guarded against. As soon, however, as fresh cells were inoculated into the media, growth took place with the resulting fermentative or other changes characteristic of their specific activity. Following his studies on the fermentation of organic substances by living microorganisms, Pasteur turned his attention to the nature of disease, first of all in silkworms and bees, and later in animals and man. During the ensuing years he proved beyond doubt that many diseases were associated with the growth in the tissues of a specific microorganism, and in spite of intense opposition from the medical profession he revolutionized the whole conception of transmissible disease.

The German bacteriologist Robert Koch (1843–1910) introduced technical methods for obtaining different microorganisms in pure culture and described the bacterial agents responsible for tuberculosis and cholera. Pupils of Pasteur and Koch discovered the causative microorganisms of a whole range of different diseases. Joseph Lister (1827–1912) at Glasgow, Scot., applied Pasteur's teaching to the prevention of sepsis in wounds, with results so striking that a new era in surgery was begun. Agricultural studies revealed that soil fertility was essentially dependent on microbial action, and plant pathology was illuminated by the discovery of pathogenic bacteria and viruses. Infectious diseases in the animal and vegetable world are known to be caused by the action of specific microorganisms, and methods of diagnosis and treatment are but a natural sequence of the fundamental researches of Pasteur.

II. CAUSES OF DISEASE

1. Etiology.—The ways in which the specific role of a microorganism in the causation of a given disease is established are summarized in what are referred to as Koch's postulates: (1) the microorganism should be present in all cases of the disease, its distribution within the body being in general conformity with the nature and site of the pathological lesions; (2) the microorganism should be isolated from the diseased tissues and grown in pure culture outside the body for a number of generations; (3) administration of the microorganism in pure culture to a susceptible animal should give rise to the disease in question, and the microorganism should be recovered from the tissues of the diseased animal. In most bacterial infections these postulates can be fulfilled; exceptions do occur, such as in leprosy, where the last two have not yet been satisfied. The presence of the leprosy bacillus in the tissues, however, is so uniformly associated with the disease that, in spite of the continued failure of bacteriologists to cultivate it in artificial media and so reproduce the disease with pure cultures, no one has any serious doubt of its etiological significance.

In rickettsial and virus infections these postulates are not easy to satisfy, mainly because of our inability to cultivate the microorganisms of these diseases in lifeless media. The second postulate was therefore modified to include the use of tissue cultures and the chick embryo for purposes of growth, even though the purity of the culture under these conditions cannot be guaranteed.

With the smaller viruses there is difficulty in fulfilling even the first postulate, since they are below the limit of resolution of the microscope and cannot be distinguished with certainty from inanimate particles. In virus work the microscope is largely replaced by the use of graded ultrafilters and the high-speed centrifuge, both of which help to determine the size and, to some extent, shape of the virus particles, though the electron microscope is helping to overcome the limitations of ordinary microscopical equipment.

Since Koch's time other methods have been introduced that help to prove the etiological role of any given organism. These comprise particularly the appearance in the blood stream of immune bodies following an attack of the disease, and their specific action in agglutinating or lysing the suspected organism, or in neutralizing its infectivity or toxicity.

2. Agents Producing Infectious Disease.—Microorganisms commonly producing disease may be classified as follows:

Bacteria.—The chief diseases caused by these organisms are enumerated in the table. Pathogenic bacteria vary greatly in their infectivity and invasiveness. Most species multiply in the internal tissues and produce their effect by the formation of so-called endotoxins. A few, like the diphtheria and the tetanus bacillus, multiply locally and produce their effect by the formation of a powerful exotoxin, which is carried by the blood stream to other parts of the body. *Clostridium botulinum* is not a parasite at all. It forms a potent exotoxin by growth in food kept under favourable conditions, and the resulting disease is therefore a toxemia rather than an infection.

Rickettsiae.—These are small organisms whose natural habitat is the intestinal canal of arthropods. A few species have become adapted to man and give rise to such diseases as typhus fever, Rocky mountain spotted fever, tsutsugamushi (scrub typhus), Q fever and trench fever. Infection is carried to man by lice, fleas, ticks and mites.

Viruses.—These organisms are even smaller than the rickettsiae, are mostly below the limit of ordinary microscopical resolu-

Main Groups of Pathogenic Bacteria and the Diseases Caused by Them

Bacterial genus	Chief pathogenic species and types	Natural diseases produced	Special treatment	Remarks
Actinobacillus	*Actinobacillus lignieresi*	Wooden tongue in cattle	—	Probably noninfective for man
Actinomyces	1. *Actino. bovis* (microaerophilic)	Actinomycosis in man and cattle (lumpy jaw)	Penicillin, terramycin, chloramphenicol and aureomycin	Not highly infectious; mode of transmission doubtful
	2. Numerous aerobic species	Madura foot in man, farcy of cattle and other granulomatous lesions	—	—
	3. *Actino. muris* (*Streptobacillus moniliformis*)	One form of rat-bite fever in man and infective arthritis of mice	—	Normal parasite of the rat's nose
Bacillus	1. *B. anthracis*	Anthrax in animals; malignant pustule and woolsorters' disease in man	Aureomycin, penicillin and specific antiserum	—
Bartonella	1. *Bart. bacilliformis*	Oroya fever and verruga peruana in man	Possibly chloramphenicol	Infection carried by sand flies
	2. *Bart. muris*	Infectious anemia of rats	Arsenic and antimony	Infection carried by rat lice
	3. *Bart. canis*	Infectious anemia of dogs	—	Infection carried by dog fleas
Brucella	1. *Br. melitensis*	Septicemic infection of sheep and goats; brucellosis in man	Terramycin and aureomycin	Occurs chiefly along Mediterranean littoral
	2. *Br. abortus*	Contagious abortion of cattle; brucellosis in man	Terramycin and aureomycin	Universal distribution
	3. *Br. suis*	Local or general infection of pigs; brucellosis in man	Terramycin and aureomycin	Occurs mainly in middle west of U.S.
	4. *Br. tularensis* (classified by some as *Past. tularensis*)	Plaguelike disease in rodents and occasionally in man	Chloramphenicol	Occurs in Rocky mountains, U.S.S.R., Norway, etc.
Clostridium	1. *Cl. tetani* (anaerobic)	Tetanus in horses and man (lockjaw)	Toxoid for prevention; antitoxin for treatment	—
	2. *Cl. botulinum* (anaerobic)	Botulism in man, limberneck in chickens and ducks, forage poisoning in horses, lamziekte in cattle	Antitoxin	Conveyed to man and animals by toxic food
	3. Several species, such as *welchii, septicum, oedematiens, bifermentans, histolyticum* (anaerobic)	Gas gangrene in man *Cl. welchii* may give rise to one form of food poisoning	Antitoxin	Disease follows wound infections
Corynebacterium	1. *C. diphtheriae*	Diphtheria in man	Toxoid for prevention; antitoxin for treatment	Specific human parasite
	2. Several species	Pseudotuberculosis in sheep and mice, suppurative lesions in cattle, pyemia in horses, etc.	—	Not transmissible to man
Erysipelothrix	1. *Ery. rhusiopathiae*	Swine erysipelas, erysipeloid in man, septicemia in mice	Vaccines and antisera in pigs and antiserum in man	—
	2. *Ery. monocytogenes*	Infective mononucleosis of rabbits, meningoencephalitis of various animals and other lesions	—	Occasionally infective for man
Escherichia	*Esch. coli*	Gastroenteritis in infants; white scours in calves	Possibly sulfadiazine and chloramphenicol	Only certain types of this organism are pathogenic
Fusiformis	Multiple species (anaerobic or microaerophilic)	Suppurative lesions in numerous animals and occasionally in man	—	Found mainly in necrotic lesions
Haemophilus	1. *H. influenzae*	Secondary invader in respiratory infections; occasionally meningitis	Meningitis susceptible to streptomycin and antiserum	Multiple serological types
	2. *H. pertussis*	Whooping cough in man	Vaccines in prophylaxis	Specific human parasite
	3. *H. ducreyi*	Soft chancre (venereal disease in man)	Sulfonamides or antibiotics	Specific human parasite
	4. Some other species	Infections in dogs, pigs and other animals	—	—
Leptospira	1. *Lepto. icterohaemorrhagiae*	Weil's disease in man	Possibly penicillin	Normal parasite of rats
	2. Numerous other species	Autumn fever of Japan, coastal fever of Queensland, swamp fever, etc., in man	—	Primarily parasites of rodents. Several different animals affected
Mycobacterium	1. *Myco. tuberculosis*—human type	Tuberculosis in man, pigs, monkeys, dogs, parrots	Favourably influenced by streptomycin, isoniazid and P.A.S.	Primarily a human parasite
	2. *Myco. tuberculosis*—bovine type	Tuberculosis in man, cattle, pigs, monkeys, dogs, cats, sheep, goats	Favourably influenced by streptomycin, isoniazid and P.A.S.	Primarily a bovine parasite. Causes some nonpulmonary tuberculosis in man
	3. *Myco. tuberculosis*—murine type	Tuberculosis in voles	—	Noninfective for man
	4. *Myco. tuberculosis*—avian type	Tuberculosis in fowls and other domestic birds and sometimes in wild birds; also pigs	—	Practically never infects man
	5. *Myco. tuberculosis*—cold-blooded type	Tuberculosis in cold-blooded animals and fish	—	Noninfective for man
	6. *Myco. leprae*	Leprosy in man	—	Another type gives rise to rat leprosy
	7. *Myco. johnei*	Johne's disease in cattle and sheep	—	Progressive type of pseudotuberculous enteritis

Main Groups of Pathogenic Bacteria and the Diseases Caused by Them—(Continued)

Bacterial genus	Chief pathogenic species and types	Natural diseases produced	Special treatment	Remarks
Neisseria	1. *N. meningitidis*	Cerebrospinal fever in man	Sulfonamides and penicillin	Specific human parasite
	2. *N. gonorrhoeae*	Gonorrhea in man	Sulfonamides and penicillin	Specific human parasite
Pasteurella	1. *Past. pestis*	Plague in numerous species of rodents and in man	Sulfadiazine, streptomycin and chloramphenicol	Infection transmitted by fleas
	2. *Past. septica*	Hemorrhagic septicemia in numerous animals	—	Occasionally pathogenic for man, as after a cat bite
	3. *Past. pseudotuberculosis*	Pseudotuberculosis in rodents	—	Rarely infective for man
Pfeifferella	1. *Pf. mallei*	Glanders and farcy in horses, glanders in man	—	Has been eliminated from Great Britain
	2. *Pf. whitmori*	Primarily affects rodents; melioidosis in man	—	Usually fatal in man
Salmonella	1. *Salm. typhi*	Typhoid fever in man	Vaccine for prophylaxis. Antiserum and chloramphenicol for treatment	Specific human parasite. Numerous Vi-phage types recognized
	2. *Salm. paratyphi* (*A, B and C*)	Paratyphoid fever in man	Vaccine for prophylaxis	Probably specific human parasites
	3. Over 300 species of the so-called food-poisoning group differing in antigenic structure	Food poisoning or typhoid-like fevers in man; enteritis in rodents and domestic animals	Furazolidone in animals	Primarily parasites of rodents, fowls, pigs, cattle, etc.
Shigella	Numerous species, such as *shigae, schmitzi, flexneri, boydi, sonnei*	Bacterial dysentery in man	Sulfonamides	Numerous types of *flexneri* and *boydi* species. Specific human parasites
Spirillum	*Spirillum minus*	One form of rat-bite fever in man	Arsenic and possibly penicillin	Normal parasite of rats and mice
Staphylococcus	*Staph. aureus*	Localized suppurative lesions in man and animals, particularly boils, wound infections and mastitis, and one form of food poisoning	Sulfonamides, penicillin, terramycin and aureomycin	*Albus* species much less pathogenic
Streptococcus	1. *Str. pyogenes* (Group A; β-hemolytic)	Scarlet fever, tonsillitis, erysipelas, puerperal fever and possibly rheumatic fever in man; occasionally mastitis in cattle	Sulfonamides and penicillin	About 30 serological types
	2. *Str. agalactiae* (Group B)	Mastitis in cattle	Sulfonamides	Low degree of infectivity for man
	3. Groups C to N	—	—	Groups D and G occasionally infective for man
	4. *Str. pneumoniae* (α-hemolytic)	Pneumonia in man and some animals	Sulfonamides and penicillin	77 serological types recognized
	5. Numerous other species of the α-hemolytic or viridans type	Occasionally infective endocarditis and other lesions in man	Penicillin	—
Treponema	1. *Trep. pallidum*	Syphilis in man	Arsenic and penicillin	Specific human parasite
	2. *Trep. pertenue*	Yaws in man	Arsenic and penicillin	Tropical disease, nonvenereal, spread by contact and insects
	3. *Trep. recurrentis*	Relapsing fever in man	Arsenic and antimony	Transmitted by blood sucking insects
Vibrio	*V. cholerae*	Asiatic cholera	Possibly sulfonamides	Specific human parasite

tion, usually pass through bacterial filters, cannot be cultivated in the absence of living tissue and vary greatly in the range of species they attack. Some viruses are specific parasites of man, others of animals, and some infect both man and animals. Infection is often air-borne, but it may occur by insect bites or occasionally by food. These organisms are responsible for a wide range of diseases.

Yeasts and Fungi.—Several yeasts or yeastlike fungi are pathogenic for man, such as the causative organisms of thrush (*Candida albicans*) and several infections of the lung (*see* RESPIRATORY SYSTEM, DISEASES OF; THRUSH). Several typical fungi, of which the commonest is ringworm, are of importance in human pathology.

Protozoa.—The main diseases of man caused by these unicellular organisms are malaria, trypanosomiasis, leishmaniasis and amoebic dysentery. Apart from the last, they are carried by bloodsucking insects.

III. SPREAD OF DISEASE

1. Epidemiology.—Numerous factors determine the prevalence of a given disease in a community, such as the mode of transmission of the disease, the virulence of the infecting organism, the age, sex, occupation, nutritional state and degree of immunity of the exposed population, climatic conditions and so on. As each of these may vary independently, it is usually impossible to predict without more knowledge than is generally available what course a particular infection is likely to run when introduced into a community. Broadly speaking, bacteria may gain access to the body by the respiratory tract, by the alimentary tract, by wounds or abrasions in the skin or by direct inoculation, as through insect bites.

Infections via the Respiratory Tract.—Several pathogenic bacteria are able to attack the mucosae lining the upper respiratory tract (*i.e.*, the nose, mouth and nasopharynx) and give rise to disease; notable among these are the diphtheria bacillus, the streptococcus responsible for scarlet fever and tonsillitis, and the whooping-cough bacillus. Patients suffering from these diseases are infectious to others, because they may expel the causative organism into their surroundings, particularly by sneezing and coughing. The same applies to infections of the lower respiratory tract, including the lung, with organisms such as the human tubercle bacillus and the pneumococcus. Multiple droplets of saliva and mucus, varying in size, are expelled with explosive violence forming a cloud of so-called cough spray. Many of these contain the infecting organism and are therefore dangerous to other people if inhaled. C. Flügge at the end of the 19th century was the first to draw attention to this method of droplet infection, especially in respect to pulmonary tuberculosis, and the subject thereafter received considerable study from British and U.S. workers.

W. F. Wells in the United States showed that the fate of the droplets depends mainly on their size. The rate at which they fall is proportional to the square of their diameter. The larger droplets, of one millimetre or more in diameter, fall in a curved trajectory to the ground, where they settle and may dry up to form dust. Those with a diameter of less than one-tenth millimetre evaporate so rapidly in unsaturated air that they never reach the ground but remain suspended as droplet nuclei. These behave much like a gas and can be carried by air movements over considerable distances. Droplets with a diameter between one-tenth millimetre and one millimetre may reach the ground before they evaporate or may become transformed into droplet nuclei, depending on the height from which they are liberated, the degree of saturation of the atmosphere and other factors.

It will be seen, therefore, that infective particles may reach the respiratory tract either in the form of dust, of droplets or of droplet nuclei. Droplet infection is restricted to persons in the immediate vicinity of the sneeze or cough, since the droplets fall to the ground within five or six feet after being expelled by a standing person of normal height. On the other hand, they may be heavily infected with bacteria, and their direct passage within a second ensures that the organisms are unaltered by exposure to inimical agencies in the outside world. The droplet nuclei are carried much farther, but on the other hand are less often infected than the larger droplets and may be exposed to influences such as sunlight that are harmful to the contained microorganisms. Dust may result from the drying of large droplets that have fallen to the ground, or of gross particles of sputum that have been expectorated. Though G. Cornet in the 19th century believed that dried sputum constituted the chief source of infection in pulmonary tuberculosis, the teaching of Flügge led to a considerable modification in this view; later the pendulum swung back, and many experimentalists by the mid-20th century regarded dust as an important vehicle of infection. It must be remembered, however, that the atmospheric conditions in cold damp climates are often unfavourable to complete desiccation of sputum, and that out-of-doors the sterilizing effect of sunlight may lead to a gross loss in its infectivity. Moreover, desiccation by itself often has a destructive effect on bacteria so that the infectivity of dust and of droplet nuclei may well be less than that of directly inhaled droplets. It is probable that all three forms of infective material—dust, droplets and droplet nuclei—play a part in causing respiratory infection, the exact part in any particular instance depending on a number of variable factors.

Infections via the Alimentary Tract.—Most infections that are conveyed by this route give rise to some form of inflammation of the alimentary tract so that the infective material itself is usually derived from the excreta. There are, however, exceptions to this rule. The upper part of the alimentary tract (namely, the throat) is shared by the respiratory tract; and some diseases, such as scarlet fever and diphtheria, that are normally acquired by respiratory infection may be caused by the consumption of food contaminated with the cough spray of patients, or by milk derived from cows whose udders or teats are infected with the causative organisms of these diseases. Another exception is the bovine tubercle bacillus, which is ingested in milk, passes through the lymphatic tissue in the throat or intestine and gives rise to disease in the bones, joints, glands, meninges or other organs but not usually in the alimentary tract itself.

Apart from these, and some other milk-borne diseases such as brucellosis, infection via the mouth occurs directly or indirectly from the feces by ways that may be summarized in three words: fingers, food and flies. Fingers of patients and carriers suffering from intestinal infections are almost invariably contaminated after a visit to the lavatory and, unless they are washed immediately, are liable to contaminate every object with which they come into contact. Other persons handling the same objects pick up the infecting organisms and may transfer them with their fingers to the mouth, nose or conjunctiva, whence they reach the throat and are swallowed. The danger of contaminated fingers is greatest in cooks and other persons concerned in the preparation and handling of food, because many food substances act as excellent media for the growth of intestinal bacteria. If the food is kept at a suitable temperature, prodigious bacterial multiplication may occur, and persons consuming the food are exposed to grave risk of disease. The most favourable foods for bacterial multiplication of this sort are milk, custard, gravy, soup and made-up meat dishes, such as stews, pies, sausages, pressed beef and brawn. Food may be contaminated from other sources than fingers, particularly dust and flies. In countries or places where the water carriage system of sewage disposal is not practised, fecal material deposited on the ground may dry up and be blown about in the form of dust, or particles may be transferred to food by flies. Shellfish that are laid down in sewage-polluted estuaries are regularly contaminated with intestinal bacteria, and if pathogenic forms, such as typhoid bacilli, happen to be among them, they may render the shellfish dangerous for human consumption.

Infections via Wounds and Skin Abrasions.—The skin forms an excellent defense mechanism for the body, protecting the underlying tissues from infection. With a few doubtful exceptions, no pathogenic organisms are able to penetrate the intact skin. The presence, however, of small abrasions, and still more of actual wounds, enables pathogenic organisms in contact with them to pass to the subcutaneous tissue or muscle and either set up disease locally or be transferred by the lymph and blood streams to other parts of the body where they may proliferate. Venereal disease is spread by direct contact of the skin (or mucous membranes) with an infected surface; boils result from the ingress of staphylococci, often at a site subject to irritation or pressure.

Infections Borne by Insects.—Bloodsucking insects play an important part in the transmission of certain diseases. Sometimes, as in malaria, the organisms in the capillary blood are ingested by a mosquito, undergo proliferation in the insect's body and after a few days reach the salivary glands, whence they may be injected into the skin of persons bitten by the mosquito. Sometimes, as in typhus fever, the organisms multiply in the lining of the intestinal tract of the body louse and are deposited in feces on the skin of an infested person and then get rubbed into the skin at the site of the insect's bite as the result of scratching. In most insect-borne diseases the main reservoir of infection is an animal, and man becomes infected more or less incidentally; in a few, like malaria and possibly louse-borne typhus, man constitutes the sole mammalian host.

2. Virulence and Immunity.—By virulence is generally meant the power of the organism to invade the body of the host, to multiply in the tissues and to produce disease. These factors, however, are affected by the degree of immunity of the host. An organism that is highly virulent for a person with a low degree of immunity may be comparatively avirulent for another person with a high degree of immunity.

Both virulence as applied to the microorganism and immunity as applied to the host are relative terms. It is true that an organism may be described as completely avirulent or a host as completely insusceptible, but these conditions usually apply only to nonpathogenic bacteria to which a given host possesses absolute immunity. Normally, virulence and immunity have to be defined relatively. One strain of organism may be shown to be more virulent than another, or one host more immune than another; but it is impossible to say that an organism has a given degree of virulence independent of the degree of immunity of the host. (*See* IMMUNITY AND IMMUNIZATION.)

Bearing this in mind, it may be said that different species of organisms vary greatly in virulence, and that the same organism may exhibit differences in virulence from time to time. An organism like the foot-and-mouth virus is practically avirulent for man, seldom giving rise to disease. An organism such as the human tubercle bacillus has a relatively high degree of infectivity, but in only a small proportion of infected persons does the organism multiply sufficiently in the tissues to give rise to evident tuberculosis. An organism such as the measles virus, on the other hand, has not only a high degree of infectivity but is able to produce the characteristic disease in practically every nonimmune person with whom it comes into contact.

The result of infection, therefore, in any given host is deter-

mined by the balance of virulence and immunity. In a highly immune person the infection may be completely resisted and the organisms destroyed before any damage is done. In one rather less immune, the organism may be able to establish itself in the tissues, but be unable to produce any serious lesion; such a person becomes a so-called healthy carrier. In one still less immune, the organism multiplies to a certain extent, produces mild systemic disturbance (subclinical attack) and is then overcome by the resisting forces of the body. In a normally susceptible person the organism establishes itself in the tissues, multiplies freely, produces its toxic substances and gives rise to a typical attack of the disease. In an abnormally susceptible person in whom the natural defense mechanism of the body is defective, rapid proliferation of the invading organism occurs with the production of a fulminant attack of the disease. Whether the illness proves fatal or not depends on the natural virulence of the organism and the degree of immunity of the host. Some diseases have a much higher case fatality than others.

Of special interest to the epidemiologist is the apparent increase in virulence that may occur in a given organism from time to time. It is always tempting to explain a major epidemic prevalence of a particular disease as the result of an increase in the virulence of the infecting organism, but it is difficult to prove beyond all measure of doubt that such an increase does in fact occur under natural conditions. Usually the fluctuations in epidemic prevalence of an endemic disease are determined mainly by the level of herd immunity. Measles, for example, in most civilized communities attacks young children. As the virulence of the organism is high, practically every exposed child develops the disease, and those who recover are left permanently immune. The disease, therefore, dies down, not because of any loss in virulence of the organism, but because the supply of susceptible hosts tends to become exhausted. For the next year or so the prevalence of the disease remains low, until a large enough population of young susceptible children has grown up to enable a fresh outbreak to occur.

It is difficult, however, to explain all epidemic manifestations in this way. Influenza, for example, is a disease that attacks the population of any given country every few years, producing a fairly large number of cases but comparatively few deaths. Every now and again, however, it assumes a much more serious character. This is illustrated by the pandemic of 1918–19, when the disease swept over the entire world, killing more persons in its train than World War I itself.

There is nothing to suggest that the general level of immunity to influenza was any lower in 1918–19 than it was in the 20 years before or after the outbreak, and we are therefore driven to assume that a particularly virulent strain of virus had developed that was able to overcome the resistance of a high proportion of the persons who were exposed to attack. What mechanism is responsible for the development of these hypervirulent strains it is impossible to say. Variation is constantly occurring in microorganisms, and it can only be supposed that occasionally a particularly virulent variant arises under conditions that favour its rapid transmission from host to host and so enable it to assume temporary predominance over other variants with the resulting production of widespread disease.

3. Other Factors Affecting the Prevalence of Diseases.—Age, sex and occupation all have a bearing on the incidence of infectious diseases. Many infections are confined mainly to childhood and leave behind them an immunity that serves to protect the host when re-exposed during adult life. Infancy and early childhood are generally the periods of greatest susceptibility, though by no means always. Typhoid fever, for instance, is much commoner, at any rate in its typical form, in adults than in children. Old age is a period when the resistance of the body begins to weaken, and death frequently results from so-called terminal infections that would be relatively harmless in the prime of life.

The difference in susceptibility between the sexes is usually small, though a striking exception is afforded by the much higher incidence of pulmonary tuberculosis in young adult females than males. Certain occupations predispose to infection, either because the work is carried on under conditions that favour exposure to, or transmission of, infection (as in the relatively high incidence of anthrax among hide porters), or because the person's resistance to some organism with which he is already infected but with which he has established an equilibrium is disturbed by factors dependent on his occupation (such as the effect of inhaled silica in predisposing to pulmonary tuberculosis in hard-coal workers and knife grinders).

Though defective nutrition is popularly believed to predispose to infection, there is comparatively little evidence to show that, so far as the acute infectious diseases are concerned, it has more than a minor effect. Measles, for example, appears to be just as common in the well-fed as in the poorly fed child, and the same holds true of many other infectious diseases. Only when there is a gross deficiency of certain constituents of the diet, particularly vitamin A, does the resistance appear to be seriously affected. On the other hand, there is a good deal of evidence to suggest that inadequate nutrition does enable the tubercle bacillus, with which a high proportion of European adults are latently infected, to give rise to overt disease, which would normally be held in check in persons who were better nourished. The widely held assumption that infectious disease would not occur in a properly fed people is entirely without foundation.

The effect of climate on infectious disease is difficult to separate from other factors. Enteric diseases are commoner in warm, and respiratory diseases in cold, countries; but the former can be explained largely by the greater opportunities for infection from improperly disposed excreta and the lower level of personal hygiene in those preparing food, and the latter by the greater ease with which respiratory infection spreads under overcrowded indoor conditions. On the whole, the available evidence does not suggest that climate by itself has any great influence on the prevalence of infectious disease.

4. Endemic and Epidemic Diseases.—In civilizations that have been long in contact with a particular microorganism, a state of equilibrium has usually become established whereby the organism is widely spread in the community without giving rise to extensive fatal disease. An endemic prevalence of this sort is often possible only by the elimination of the more genetically susceptible members of the community in the earlier generations, followed by breeding from those having a higher genetic resistance. Examples of two widespread diseases in which this appears to have occurred in Great Britain are tuberculosis and syphilis.

Epidemic prevalence of an endemic disease is determined by many factors that are only imperfectly understood. A sufficiently high proportion of the population must be susceptible, and the means for sufficiently rapid transmission of the infecting agent must be available. In a disease like influenza an epidemic is preceded by an increasing number of sporadic cases. The proportion of cases rises rapidly to a maximum, then falls progressively till the usual endemic level is regained. The rise and fall usually occur at about the same rate so that the cases, if plotted on a graph, form a symmetrical curve. In typhoid fever, on the other hand, an outbreak of the disease is generally confined to a particular section of the population which has been exposed to an unusual source of infection such as the consumption of contaminated water, milk, ice cream or shellfish. Outbreaks of this sort tend to be explosive; the upward limb of the curve is steep, but the downward limb, because of the occurrence of secondary cases, tends to be flatter and is often prolonged for several weeks.

Other forms of epidemic prevalence are seen in other diseases depending on factors that are too numerous or complex to be specified here.

5. General Features of Infectious Diseases.—The incubation period elapsing between the access of the infecting organism to the body and the appearance of manifest symptoms of disease varies greatly. At one end of the scale is acute streptococcal septicemia following, for instance, a wound received while carrying out a post-mortem examination, which may be fatal within 24 hours. At the other end is a disease such as leprosy in which infection may not be followed by clinical evidence of disease for several

years. In most of the acute eruptive fevers (such as measles) the incubation period ranges from two or three days to two or three weeks. Longer incubation periods of six weeks or so are seen in diseases such as rabies and brucellosis, and in tuberculosis a year or two often passes between infection and manifest disease.

In the acute fevers the incubation period is probably indicative of the time taken for the organism to multiply sufficiently in the tissues to bring about serious disturbance in the economy of the host. In tuberculosis, on the other hand, though disease may follow within a few weeks of infection, it is commoner for the organism to give rise to a latent infection, detectable only by special tests, which after a variable period may progress to the stage of manifest disease or may gradually undergo retrogression and healing. A delicate equilibrium is set up between the parasite and the host, which is liable to be disturbed by any factor leading to a temporary reduction in the natural defense mechanism of the body.

Infection with any parasite gives rise to a series of reactions on the part of the tissues. The commonest of these is the phenomenon of inflammation (*q.v.*), which is characterized by vascular and cellular changes tending to localize the site of infection and to destroy the invading organism. Inflammation is a general reaction seen in some form or other in practically all living matter and results not only from attack by microorganisms but from the introduction into the tissues of any irritant substance. Infection by microorganisms gives rise to an additional series of reactions that are specific to each individual type of organism. Special substances, known as antibodies, are produced in certain cells of the body, collectively known as the reticulo-endothelial system, which act on the particular type of microorganism that is responsible for infection. The union between the antibody and the corresponding substance in the microorganism, referred to as the antigen, is highly specific, resembling a lock-and-key mechanism; and when antibodies are present in sufficient quantity, they act on the microorganism in various ways, bringing about a change which renders it vulnerable to attack by the normal phagocytic cells of the blood and tissues. Specific immunity acquired in this way may be lifelong or comparatively transient. If the former, then a second attack of the particular disease is improbable; if the latter, second, third and fourth attacks may occur at quite short intervals.

Little knowledge is yet available concerning the factors that determine the degree and duration of acquired immunity in different diseases. Generally speaking, the disseminated virus infections give rise to a strong and permanent immunity, the bacterial respiratory infections to a relatively weak and transient immunity.

IV. CONTROL

1. Prevention.—Prevention of infectious disease may be attempted in three ways: diminution in the amount of infective material, control of the means of transmission and increasing the resistance of the host.

Attempts to diminish the amount of infective material comprise a wide variety of measures depending on the nature and source of the infective material. Spitting and sneezing or coughing except into a handkerchief should be avoided. Patients suffering from infectious disease should be isolated, and carriers may need to be segregated or restricted in their occupations. In practice, this is often difficult. Little or no objection, for example, is raised to the isolation of patients suffering from diphtheria or smallpox, but the isolation or even the segregation of tuberculous persons is much more difficult to effect. Quarantine may have to be imposed on ships carrying plague, cholera, smallpox and yellow fever. Here again, social and economic difficulties usually prevent the use of this method except in a limited form. Experience has shown that attempts to impose strict quarantine almost invariably fail. The compelling urgency of personal business results in a breaking of the sanitary cordon.

Much better results are obtained by a policy of partial supervision. Healthy passengers are allowed to leave the ship and proceed to their destinations. The medical officer of health of the district to which they are going is notified, and the passengers themselves are asked to report to a doctor at once if they become ill. In this way a correct diagnosis can be rapidly made in contacts developing the disease, and the patients themselves removed to a hospital.

Destruction of the infective agent by heat or chemical disinfectants is useful in particular circumstances but is seldom practicable on a large scale. In air-borne infection adequate ventilation of buildings constitutes one of the most important methods of protection, since it reduces the total number of microorganisms in the atmosphere and so lowers the risk of any occupant's receiving a dose larger than his tissues are able to cope with at any one time. Cleanliness and avoidance of dust are likewise of value. Sunlight has a sterilizing effect on bacteria so that the traditional methods of soap and water, open windows and removal of blinds and curtains to let in the maximum amount of light are all well supported by scientific evidence.

Where climatic conditions are unfavourable, destruction of microorganisms in the air of the room may be attempted by ultraviolet light irradiation and by the use of finely divided disinfectant sprays, known as aerosols. These methods, however, are still in the experimental stage and are at best poor substitutes for sunlight and fresh air.

Control of the means of transmission of the infecting agent had its most striking success in the intestinal group of diseases. Provision of a pure water supply in Great Britain has led to the eradication of cholera and to a great reduction in the incidence of enteric fever. In the larger cities of the United States compulsory pasteurization of milk resulted in the practical elimination of milk-borne disease.

Much greater care, however, is still needed in the hygienic handling of food. Veterinary inspection of animals before slaughter, the provision of properly equipped and controlled abattoirs, the examination by qualified inspectors of meat after slaughter, the institution of sound hygienic practices in food-processing plants, the education in hygiene of all persons handling food, a revision of the system of communal feeding (which presents problems differing from those met with in the domestic kitchen and requiring special technique for their solution), improved methods of storage and distribution of food, destruction of rats and mice and the control of flies and other insects are some of the measures required if food-borne diseases are to be avoided.

The strict enforcement of muzzling in countries where rabies (hydrophobia) is spread by dogs can lead, in conjunction with a rigid system of control of imported animals, to the complete disappearance of the disease.

In the prevention of diseases caused by bloodsucking insects, considerable success has attended the destruction of breeding places and the killing of the larvae by chemical agents.

The resistance of the exposed population may be increased to some extent by the usual hygienic measures such as good food, regular meals, personal cleanliness, fresh air, sufficient exercise, adequate sleep and avoidance of all forms of excess; though it must be pointed out that these measures by themselves are unable to ensure freedom from infectious disease. Indeed persons in excellent physical condition coming from rural areas often prove far more susceptible than poorly developed persons brought up in the towns, who have been exposed to various infections in early life and have acquired some degree of immunity against them.

To forestall this natural method of immunization, which, of course, is always accompanied by a considerable amount of disease and death, attempts have been made to raise the resistance of the exposed population by prophylactic vaccination. In theory, this would appear to be the most promising method of controlling infectious disease, but in practice its use is limited. There are only a few diseases against which prophylactic vaccination can be relied on to give a high degree of protection. Against the others either no vaccine is available or the degree of immunity it confers is insufficient to protect against heavy or repeated infection. Moreover, for this method to be successful, all per-

sons who are likely to be exposed to risk of infection must not only be vaccinated against each disease, but must be revaccinated at suitable intervals. This may be practicable in the armed services, but it is more difficult to ensure in civil life. Generally speaking, the protective power of a given vaccine is proportional to the degree of immunity resulting from an attack of the natural disease. That is to say, vaccination is of most value in diseases that leave behind them a lifelong immunity and in which second attacks are rare. The most conspicuous examples are some of the virus diseases, such as smallpox and yellow fever, and distemper in animals.

The next most potent vaccines are those against diseases caused by bacteria that produce a powerful exotoxin. Diphtheria and tetanus are the most striking examples. The success of diphtheria immunization has been outstanding. If it is to be used to eliminate the disease from the community and not merely to protect the individual child, a sufficiently high proportion of the population must be immunized, and this must include the most susceptible age groups. Unless the proportion immunized reaches 75% and is maintained at or about this level, and unless children are revaccinated every five years or so during school life, the disease may continue to spread. Against other bacterial diseases vaccination is less effective. It is used most frequently to protect against enteric fever, whooping cough and typhus, but the degree of immunity it produces, though valuable, is not very high.

With the exception of diphtheria (*see* above) and perhaps of whooping cough, attempts to control respiratory diseases by vaccination have so far been unpromising. (*See* also VACCINATION; VACCINE THERAPY.)

Prophylactic administration of antisera is sometimes of value when only a transient immunity is required; but this particular method is limited to diphtheria, tetanus and gas gangrene. Chemoprophylaxis, or the daily administration of a drug, may be practised when other methods of control are unsatisfactory. Mepacrine (Atabrine), for example, proved of outstanding value in the suppression of malaria during World War II, and good results were claimed by U.S. workers for sulfonamides in protecting against respiratory infections. The danger of the development of sulfonamide-resistant strains is so great, however, that these drugs should not be used prophylactically except under special conditions.

2. Treatment.—Apart from measures to relieve the patient's symptoms, treatment of infectious diseases is directed to the removal or destruction of the invading microorganisms. Where there is a focus of disease, like an infected tooth or an abscess, surgical intervention may be required; but where infection is more general, reliance has to be placed on other methods. In one disease, diphtheria, the toxin secreted by the organisms may be neutralized by the injection of adequate doses of antitoxin. Serum treatment, however, of diseases caused by organisms that do not produce a powerful exotoxin is usually of but little value. Arsenic, antimony or mercury have long been used with success in the treatment of some of the spirochetal and trypanosome diseases; but until the introduction of the sulfonamide group of drugs and of the antibiotics, no chemical agents of sufficiently low toxicity were available for the treatment of systemic bacterial infections. These two groups of compounds, however, completely changed the picture.

Since the introduction of sulfonamidocrysoidin (Prontosil) by Gerhard Domagk in 1935, large numbers of compounds belonging to the sulfonamide group have been prepared. Their greatest success has been in the treatment of pneumococcal, streptococcal, meningococcal and gonococcal infections.

How the sulfonamides act is still open to doubt, but there is general agreement that they interfere with the metabolism of the bacteria and prevent them from making use of certain substances essential for their reproduction. The antibiotic agents are products formed during the growth of certain organisms, particularly fungi. Penicillin, streptomycin, chloramphenicol, chlortetracycline (aureomycin) and oxytetracycline (terramycin) are among the most useful for the treatment of bacterial diseases. Not all bacteria are susceptible, and none of the virus infections can be influenced by these substances, but the success of chloramphenicol in tsutsugamushi (scrub typhus), one of the rickettsial diseases, holds out hope of ultimately influencing infections caused by some of the larger viruses.

Unfortunately, some bacteria may become resistant both to the sulfonamides and to the antibiotics if treatment is kept up for long, and there is a not altogether groundless fear that the resistant variants may gradually replace the normally susceptible strains of bacteria and largely nullify the value of these new drugs.

(G. S. W.)

BACTERIOLOGY is the science that deals with bacteria. Bacteriology is important because all living things, including man, owe their existence to the activities of bacteria. Without bacteria, the soil would not be fertile, and all plants and animals ultimately are dependent upon soil fertility for life-sustaining materials. Although some bacteria cause disease, scores of others are not only harmless but actually are beneficial.

One of the main objects of this article will be to show the value of bacteria. Information on bacteria that produce disease is contained in the articles BACTERIAL AND INFECTIOUS DISEASES; PARASITOLOGY; IMMUNITY AND IMMUNIZATION; and PATHOLOGY.

This survey is divided into the following sections:

I. HISTORY

1. Beginnings of Bacteriology.—It is quite clear that in such an article as this any attempt at a comprehensive survey of the

history of the subject would be out of place. It is well, however, to select a few dates so that the reader may realize that, in comparison with other sciences, bacteriology is quite young. In the middle of the 19th century bacteria were known only to a few experts and in a few forms as curiosities of the microscope, chiefly interesting for their minuteness and motility. The beginnings of bacteriology ran parallel with the development of the microscope. The first compound microscope was introduced by Z. Janssen in 1590. This instrument gave only small magnification and it is doubtful whether A. Kircher, who wrote in 1659 of "minute living worms in putrid meat, milk, vinegar, etc.," had seen anything smaller than protozoa or possibly the larvae of insects. The first to see microorganisms was probably the Dutch naturalist A. van Leeuwenhoek, who in 1683 sent a paper to the Royal society in London in which he described some animalculae, as they were then called, in water, saliva and dental tartar. These had been seen with a simple lens magnifying about 100–150 diameters. The organisms seem to correspond with some of the very large forms of bacteria as now recognized. In 1762 M. A. Plenciz propounded a theory of infectious disease, namely, that a special organism is associated with each disease and that the organisms are capable of reproduction outside the body and can be carried from place to place by the air. In this enlightened view, Plenciz was well in advance of his time, for little was known of these minute creatures before 1860. Great assistance came with the introduction of the oil-immersion lens by G. Dollond in 1844; although the use of this instrument made magnifications of 1,000 diameters possible, the definition at this magnification was very imperfect until the light was focused on the object by means of the substage condenser. E. Abbe introduced his condenser in 1870 and C. Zeiss completed the present-day microscopic equipment with his apochromatic lenses in 1880. It is clear that bacteria were recognized before they were distinctly seen. O. F. Müller knew several important forms in 1773, while F. Ehrenberg in 1830 had advanced to the commencement of a scientific separation and grouping of them, and in 1838 had proposed at least 16 species, distributing them into four groups or genera. Our modern, more accurate knowledge of the forms of bacteria, however, dates from F. J. Cohn's brilliant researches, the chief results of which were published at various periods between 1853 and 1872. Cohn's classification of bacteria, published in 1872 and extended in 1875, in fact dominated the study of these organisms thereafter. He based his classification on what may be considered the constancy of forms that he called species and genera. The fact that some bacteria produce spores appears to have been discovered by Cohn in 1857.

While various observers added to the knowledge of the morphology of bacteria, others laid the foundation of what is known about the relations of the organisms to fermentation and disease. When L. Pasteur in 1857 showed that lactic fermentation depends on the presence of an organism, it was already known from the researches of T. Schwann (1837) and H. L. F. von Helmholtz (1843) that fermentation and putrefaction are intimately connected with the presence of organisms derived from the air, and that the preservation of putrescible substances depends on this principle. In 1862 Pasteur placed it beyond reasonable doubt that production of ammonia by the fermentation of urea is caused by the action of a minute bacterium. In 1864 this was confirmed by P. van Tieghem, and in 1874 by Cohn, who named the organism *Micrococcus ureae*. Pasteur and Cohn also pointed out that putrefaction is but a special case of fermentation, and before 1872 the doctrines of Pasteur were established with respect to bacteria.

Meanwhile two branches of inquiry had arisen from the above. In the first place, the disputed question of spontaneous generation received fresh impetus from the difficulty of keeping such minute organisms as bacteria from reaching and developing in organic infusions; and, secondly, the long-suspected analogies between the phenomena of fermentation and those of certain diseases again made themselves felt as both became better understood. J. T. Needham in 1749 had declared that heated infusions of organic matter were not deprived of living beings; L. Spallanzani (1765) had replied that more careful heating and other precautions prevent the appearance of organisms in the fluid. Various experiments by Schwann, Helmholtz, M. Schultze, K. Schroeder, T. von Dusch and others led to the refutation, step by step, of the belief that the more minute organisms, and particularly bacteria, arose *de novo* in the special cases quoted. Nevertheless, instances were adduced where the most careful heating of yolk of egg, milk, hay infusions, etc., had failed—the boiled infusions, etc., turning putrid and swarming with bacteria after a few hours.

In 1862 Pasteur repeated and extended such experiments, and paved the way for a complete explanation of the anomalies; Cohn in 1872 published confirmatory results; and it became clear that no putrefaction can take place without bacteria or some other living organism.

In the hands of O. Brefeld, H. A. de Bary, J. Tyndall, J. Lister and others, the various links in the chain of evidence grew stronger and stronger, and every case adduced as one of spontaneous generation fell to the ground when examined. No case of so-called spontaneous generation withstood rigid investigation; but the discussion contributed to more exact ideas as to the ubiquity, minuteness and high powers of resistance to physical agents of the spores of bacteria, and led to more exact ideas of antiseptic treatment. Methods were also improved, and the application of some of them to surgery by Lister, Robert Koch and others yielded results of the highest value.

2. Later Developments.—The modern methods of bacteriological technique had their beginnings in 1870–85 with the introduction of the use of stains by C. Weigert in 1871 and the discovery by Koch in 1881 of the method of separating mixtures of organisms on plates of nutrient media solidified with gelatin and agar. Following closely on the introduction of this technique came the separation of pure cultures of many bacteria. In 1882 F. Löffler and F. Schulze discovered that a bacillus is the cause of glanders; in 1883 Koch isolated the organism of Asiatic cholera and the same year E. Klebs found that of diphtheria.

In 1885 A. Nicolaier observed the tetanus bacillus in pus produced by inoculating mice and rabbits with soil. It was left, however, to the famous Japanese S. Kitasato to discover the way in which these organisms could be cultivated. In 1889 he showed that previous failures in this connection had resulted from a lack of appreciation of a necessary condition, namely, absence of oxygen. W. D. Miller, a U.S. dentist, in the 1880s studied the microorganisms of the human mouth and their possible relationship to the decay of teeth.

Important discoveries came in 1880 and 1881 when Pasteur succeeded in immunizing animals against two diseases caused by bacteria. He found that old laboratory cultures of the bacterium that causes chicken cholera became attenuated, *i.e.*, lost their virulence, and produced only a mild, temporary illness when injected into healthy fowls. More remarkable, subsequent inoculation of the same birds with freshly isolated, fully virulent cultures demonstrated that the birds had acquired a marked resistance to the fowl cholera organism.

Pasteur, together with his associates C. Chamberland and P. Roux, also found that the anthrax bacillus when cultivated in broth at a temperature of 42°–43° C. (a little above its optimum temperature of 37° C.) lost a considerable measure of virulence after a few culture generations. It then proved to be relatively innocuous when injected into animals. Sheep and cattle that had been inoculated with such attenuated bacilli proved to be curiously resistant to the deadly effects of subsequent inoculation with virulent anthrax bacilli.

In other words, animals vaccinated with the cultivated bacillus showed immunity to disease when reinoculated with the deadly wild form. These findings were destined to lead to a study of the principles of immunity that underlie the prevention and treatment of disease by vaccines and immune serums. The questions as to causes and nature of the changes in the bacillus and in the host, the extent of immunity enjoyed by the latter, etc., are of the greatest interest and importance.

While the investigations on infectious disease and immunity were under way it became apparent that other activities of bacteria are also of importance to mankind. In 1878, only two years after Koch announced the discovery of the anthrax bacillus, W.

J. Burrill discovered the bacterial cause of fire blight in pears; it became apparent that certain bacteria are associated with diseases of plants. This field of investigation was later developed especially by Erwin F. Smith. The importance of some bacteria in soil and their contribution to soil fertility came to be recognized in the 1880s and 1890s. The significance of bacterial activities in many aspects of the dairy industry was recognized at about the same time.

Aside from the earlier studies on alcoholic and lactic fermentations, the further application of bacterial activities to industrial processes came a little later. Thus in a few decades the study of bacteria progressed enormously, and by the opening years of the 20th century it was recognized that the activities of bacteria bore an intimate relation to many aspects of human activity. Originally, the chief interest centred upon what bacteria do. Later, this interest became broader and came to include the study of the bacteria themselves, what they are, their relationships to each other and to various living forms.

II. NATURE OF BACTERIA

1. Appearance, Size, Cell Structure.—Bacteria are unicellular and are among the smallest living creatures known. One of the periods on this page would cover about 250,000 average-sized bacteria. Because of their minute size they are often termed microorganisms. When they are viewed through the microscope a magnification of about 1,000 × is usually used. The shape of bacteria is simple, being modeled on four main cell types, the spherical or coccus form, the rod or bacillus type, the spirally twisted spirillum, and a long filamentous type (fig. 1). Each type maintains a certain constancy of appearance under standard conditions of laboratory cultivation, but different environments may cause some modification in appearance. The dimensions of bacterial cells are usually stated in microns. A micron (μ) is $\frac{1}{1,000}$ of a millimetre or approximately $\frac{1}{25,000}$ of an inch. Many of the spherical bacteria are about 1 μ in diameter. An average-sized rod or short spiral cell is 3 μ to 5 μ long and about 1 μ across. There is considerable variation in size among different kinds of bacteria; some are smaller, others larger than the foregoing dimensions (fig. 2). Some of the longer spiral cells and the filamentous cells attain lengths of 10 μ to 20 μ or more. They are usually quite slender, however, and seldom exceed 1 μ to 2 μ in width.

FIG. 2.—APPROXIMATE SIZES AND FORMS OF CERTAIN MICROORGANISMS COMPARED WITH HUMAN RED BLOOD CELL

Each bacterial cell consists of a mass of protoplasm surrounded by a thin cell membrane that in turn is held within and presses against a rigid cell wall (fig. 3). Granules and droplets of fatty material can at times be seen in the cell. Some variability in the make-up of their protoplasm exists between one kind and another. This is indicated by their capacity to produce markedly different chemical changes that help distinguish one species from another.

The bacteria, with few exceptions, are not equipped with chlorophyll, the green colouring matter of plants.

Evidence has accumulated to show that bacteria possess a definite nucleus that can be distinguished, at least in a number of them, by the use of special methods. The nucleus commonly appears as a dumbbell-shaped or spherical body, often in pairs and at times in a group of four. The nucleus has been shown to contain a compound called deoxyribonucleic acid that is characteristic of the nuclei of the cells of other living organisms. Further, mitotic figures associated with division of the cell have been distinguished in a few cases. Thus, it appears that the components and general make-up of bacteria are basically quite similar to those of the cells of higher forms.

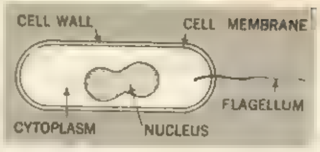

FIG. 3.—SCHEMATIC DRAWING OF STRUCTURE OF A BACTERIAL CELL

In the case of some bacteria the cell body is encased in a gelatinouslike material that is known as a capsule. Chemically this material is composed largely or entirely of polysaccharide. Often each cell is surrounded by a distinct capsule, but in some cases a mass of cells may be embedded in such material; this is termed a zoogloea. Some bacteria are provided also with thin whiplike appendages projecting from the cell body. These are termed flagellums.

There may be only one flagellum, several of them or a large number. The arrangement of the flagellums varies with different species of bacteria. Sometimes only one projects from the end of a rod-shaped or spiral cell; or they may be arranged in a tuft at one end or at both ends of the cell, and in some cases they are distributed over the whole cell surface. With the aid of flagellums some bacteria are capable of rather rapid movement.

2. Spore Formation.—Some bacteria are able to form spores. The spores present a quite different microscopic appearance from that of the original cell before spore formation. The spore is formed within the cell and for this reason is sometimes referred to as an endospore. Spores are formed usually when conditions become unsatisfactory for active metabolism and for cell reproduction.

The first visible sign of spore formation is the appearance of a light spot in the cell when viewed unstained under the microscope. This differentiated portion increases in size and after several hours appears as a distinct rounded or oval body enclosed by a wall. Having formed the spore the rest of the cell gradually disappears.

Spores are much more resistant to heat, drying, light, disinfectants and other harmful agents than the original cell. They serve to tide the organism over a period when the environment is unfavourable. Spores may remain alive for more than ten years and probably much longer, withstanding conditions of drought that would speedily kill the nonspore-forming cell. When more suitable conditions return the spore germinates and from it there develops again a cell similar to the one that originally formed the spore. This new cell, under favourable conditions of moisture, temperature and food supply, then starts active metabolism and reproduction. This continues for a time until conditions change and spores are again formed.

It is to be emphasized that some kinds of bacteria are not able to form spores. Spores are usually formed only by the rod-shaped cells, and not by all of them. Usually only one spore is formed in one bacterial cell. Upon subsequent germination of the spore, usually only one vegetative cell emerges from the spore. Thus spore formation is not ordinarily a method of multiplication. Few of the disease-producing bacteria are able to form spores. This is fortunate because much more rigorous treatments than now used

would be necessary to kill them. The chlorination of water supplies to destroy diphtheria bacilli and tubercle bacilli, for example, would be enormously complicated if these bacteria were able to form spores.

3. Physiological Characteristics.—Aside from differences in microscopic appearance bacteria exhibit great diversity in their physiological activities. The energy necessary for carrying on cell activity and the building materials needed for formation of new cells during multiplication are secured in a variety of ways. The acquisition of energy and materials, in turn, is related in large measure to the different enzymes possessed by various bacteria. Many of the common bacteria of air, soil and water are capable of digesting dead organic materials, proteins and carbohydrates, breaking them down to simpler molecules and in turn utilizing these substances. Some bacteria are unable to degrade the larger molecules but make use of simpler organic substances that diffuse through the cell membrane; examples of such substances are various sugars, organic acids, amino acids and alcohols. There are many differences as to substances utilized and end products formed.

In contrast with the foregoing are other bacteria, also found in soil and water, that are independent of preformed organic materials and are capable of obtaining energy by the oxidation of inorganic compounds. A few are equipped with a chlorophyll-like pigment, make use of the energy of sunlight and in the presence of light carry on a process akin to that of photosynthesis of green plants.

It is obvious that bacteria are extraordinarily varied in their physiological activities, much more so than in their cell shape and form. (See *Food Requirements*, below.) The marked ability of bacteria as a group to produce such a great diversity of chemical changes and end products constitutes one of the outstanding facts of the natural economy. Through the agency of the bacteria and certain other microorganisms the elements necessary for life are kept in circulation. In connection with this microbic activity certain processes or end products have been found useful to man. (See *Some Activities of Bacteria* and *Bacteriology in Industry*, below.)

III. RELATIONSHIPS AND CLASSIFICATION OF BACTERIA

1. Algal and Fungal Relationships.—In many respects the bacteria resemble some of the simpler plants, particularly the blue-green algae and some of the molds, and it is largely on the basis of this resemblance that bacteria are considered to be simple plants rather than animals. Bacteria as a group often have been referred to as Schizomycetes, that is, fission fungi. In some classifications of primitive plants, bacteria are assigned the status of a phylum, Schizomycophyta, distinct from other phyla of fungi and algae. In other outlines the Schizomycetes are given a class status.

Bacteria are distantly related to the protozoa, a large group of unicellular animals that includes the amoeba, paramecium and the causative agent of malaria.

The classification of bacteria into subgroups and smaller divisions presents some difficulties since the number of morphological characteristics is limited in these very small forms of life. However, the bacteria show a considerable diversity of physiological characteristics relative to the fermentation of different sugars and other carbohydrates, different end products formed, the ability to digest proteins, different nutritive requirements and different immune responses on the part of animals. These characteristics are used along with morphological characteristics in separating bacteria into successively narrower subgroups and finally into species. The details of classification and the technical terms applied to the subgroups can be found in bacteriology textbooks.

Certain rather simple filamentous branching forms, the actinomycetes including *Streptomyces* and others, are included with the bacteria rather than the molds. Also the long spiral forms, the spirochetes, are placed in one of the subgroups of bacteria. The proper classification of bacteria is complicated to some extent by the variability of bacteria in different environments.

2. Other Related Groups: Rickettsiae and Viruses.—There are several groups of microorganisms that, although included in the subject of bacteriology, are usually placed in a group by themselves. These are the rickettsiae and the viruses.

The rickettsiae are named after H. T. Ricketts, one of the early investigators of this group. They are small bacteria or bacterialike organisms that are primarily parasites of insects and other arthropods. Some of them also cause disease in man. Typhus and Rocky mountain spotted fever are two examples. These microorganisms fail to grow in the usual culture solutions used for the bacteria, but in cases of human disease they actually invade and multiply within certain tissue cells. In many respects they appear to be more highly parasitic than the bacteria and are often thought of as intermediate between the bacteria and the larger viruses.

The term virus is applied to a group of extremely small infectious agents that produce disease in man, animals or plants. Viruses once were called filterable viruses because of their ability to pass through a very fine filter that retains the ordinary bacteria. Other characteristics also set them apart from the bacteria. For the most part they are too small to be seen with the ordinary light microscopes; they fail to propagate in test-tube nutrient solutions used for bacteria and, in contrast, usually require the presence of living and metabolizing tissue cells. *See* VIRUSES.

IV. MULTIPLICATION OF BACTERIA

1. Mode of Reproduction.—When a bacterial cell is about to divide, the material of the cell is gradually increased until its volume is practically doubled. Spherical forms become oval and rod forms stretch to nearly double their length; the cell then either becomes constricted at the middle or a cross wall forms until finally the contents are held in two compartments.

The two new cells may adhere for some time but in many cases they separate and form two new individuals or daughter cells that ordinarily are the exact counterpart of the mother cell and of each other. Because of this method of growth some authorities regard bacteria as fission fungi.

Fission represents the chief form of reproduction for many bacterial species. Other methods of reproduction, however, have been described. Reproduction by formation of a bud that develops into a mature cell has been observed. Formation of special reproductive smaller cells (conidia) occurs in some of the higher bacteria that are related to the molds, and some investigators have claimed that conidia can be formed by most or by all bacteria. There is also evidence, based upon genetic experiments with a few species of bacteria, that a procedure analogous to a sexual process occurs at times. However, reproduction is primarily asexual.

2. Bacterial Genetics; Mutation.—From the early 1940s information has accumulated to show that the hereditary apparatus of bacteria is basically the same as that of other living organisms. At that time convincing evidence of the presence of nuclei in bacteria appeared. It was demonstrated that the nuclear bodies contained deoxyribonucleic acid. Evidence has accumulated to show that, like higher organisms, heredity in bacteria is controlled by genes. It is inferred that bacterial genes are organized into chromosomal threads within the nucleus, though direct cytological evidence of this is lacking.

Three processes are known by which genetic material may be transferred from one bacterial cell to another: (1) The transfer by diffusion of soluble deoxyribonucleic acid from one type of cell. This is termed transformation. (2) Transfer of genetic material from one cell to another with a particle of bacteriophage, termed transduction. (See *Bacteriophages*, below.) (3) Gene recombination which involves direct cell contact with temporary cell fusion. These processes have been demonstrated with only a few of the many different kinds of bacteria. How widespread their occurrence may be is not known.

Heritable variations in bacteria are in most cases the result of gene mutation and are not the result of "directed variation" caused by the environment, as commonly believed at one time. In a large population of bacteria, such as a billion cells in a test-tube culture or in a colony, a mutant may appear, either spontaneously or after application of a mutagenic agent. If the mutant possesses,

DISEASE-PRODUCING BACTERIA VIEWED THROUGH THE MICROSCOPE

1. Streptococcus pyogenes in pus. X (magnified) 1,500. Stain: Gram, neutral red. This is a common species of streptococcus and is often associated in "mixed infections" or "secondary infections." (*See* also fig. 10)
2. Staphylococcus aureus (dark spheres) and Pseudomonas aeruginosa (pink rods) in pus. X 1,500. Stain: Gram, neutral red. Micrococci are commonly found in boils, abscesses, carbuncles and other suppurative processes in man. S. aureus is characterized by the golden-yellow pigment formed in pus. Pseudomonas aeruginosa is found in man associated with streptococci and micrococci, also found in pure culture in some cases of pneumonia
3. Pneumococcus (encapsuled dark ellipses) and Neisseria catarrhalis (red spheres in clumps) in sputum. X 1,500. Stain: Gram, neutral red. The majority of pneumonia cases are caused by pneumococci
4. Meningococcus (encapsuled diplococci) from cerebrospinal fluid in epidemic cerebrospinal meningitis. X 1,500. Stain: Leishman
5. Same stained: Gram, neutral red. The diplococci are mainly intracellular
6. Gonococcus from pus in gonorrhoea. X 1,500. Stain: Methylene blue, eosin. The diplococci are mainly intracellular
7. Corynebacterium diphtheriae (rods) and a few chains of streptococci from a smear of the throat lesion in diphtheria. X 1,500. Stain: Thionin blue
8. Corynebacterium diphtheriae from 12 hours' culture on Löffler's serum medium. X 1,500. Stain: Neisser's method with methylene blue and Bismarck brown. Note the bipolar staining of the metachromatic granules
9. Corynebacterium diphtheriae: involution forms. From a 5-day agar culture. X 1,500. Often found in throat lesion. Stain: Thionin blue
10. Mycobacterium tuberculosis (human type). From sputum in a case of pulmonary tuberculosis. X 1,500. Stain: Ziehl-Neelsen's method, methylene blue. A few streptococci (blue) are seen
11. Bacillus anthracis from liver of diseased guinea pig (experimental anthrax). X 1,500. Stain: Muir's method to show Gram-positive reaction and capsule staining. (*See* also fig. 15, Plate II)
12. Bacillus anthracis from 3 days' agar culture to show spores (red) within the bacilli. X 1,500. Stain: Ziehl-Neelsen's method with 0.5 per cent sulphuric acid, methylene blue
13. Escherichia coli from case of cystitis. X 1,500. Stain: Gram, neutral red. It occurs abundantly in the intestinal tract of man and derives its name "coli" from the fact that it is found most abundantly in the colon. Though these organisms may be present in large quantities without causing specific disease, they sometimes invade the gall-bladder and bile-ducts, causing cholangitis and cholecystitis, and produce lesions of the urinary tracts, causing cystitis
14. Typhoid bacillus from young agar culture. X 1,500. Stain: Gram, neutral red. This intestinal tract organism causes typhoid fever
15. Same to show flagella: 12 hours' agar culture. X 1,500. Stain: Muir's method
16. Shigella dysenteriae (Shiga): young agar culture. X 1,500. Stain: Gram, neutral red. This is one of a group of four or more organisms of the intestinal tract causing dysentery in man

BACTERIOLOGY

DISEASE-PRODUCING BACTERIA VIEWED THROUGH THE MICROSCOPE

1. Vibrio comma: 24 hours' agar culture. X (magnified) 1,500. Stain: Carbol fuchsin. Formerly known as "Comma bacillus," causing cholera
2. Same as fig. 1, to show flagella: 12 hours' agar culture. X 1,500. Stain: Muir's method
3. Pasteurella pestis from bubo in case of Oriental plague. X 1,500. Stain: Methylene blue, eosin
4. Haemophilus influenzae (Pfeiffer) from sputum in case of influenzal pneumonia. X 1,500. Stain: Gram, neutral red. Note presence of a few pneumococci in pairs (dark). (*See* also fig. 3, Plate I)
5. Clostridium tetani showing bacilli and terminal spores ("drumsticks") from 3 days' glucose agar stab culture. X 1,200. Stain: Ziehl-Neelsen, decolourized with 5% sulfuric acid, washed (water) mordanted with saturated watery potash alum, washed (water) methylene blue. This is the blood poisoning (lockjaw) organism which grows best with a very low oxygen supply. For this reason the bacilli develop in deep, dirty wounds, though these may be relatively as small as pin pricks
6. Same as fig. 5, to show flagella: 12 hours' anaerobic agar culture. Stain: Muir's method. X 1,200. The wavy mass at top is a cluster of shed flagella
7. Clostridium perfringens from a case of gas gangrene. X 1,500. Stain: Gram, neutral red
8. Same as fig. 7, from young agar culture grown anaerobically. X 1,500. Stain: Gram
9. Same as fig. 7. X 1,500. Stain: Muir's method to show capsule
10. Clostridium septicum from subcutaneous tissue in case of malignant edema with gas gangrene. X 1,200. Stain: Methylene blue. Note numerous spore-bearing bacilli singly or in chains
11. Actinomyces bovis ("ray fungus") from lesion in tongue of cow. X 800. Stain: Gram, eosin. Note that the mycelial filaments are Gram-positive, the clubs are Gram-negative. Around the colony mononuclear cells predominate
12. Naked-eye culture of Staphylococcus aureus on gelatine slope: at the bottom the gelatine is liquefied. (*See* fig. 2, Plate I)
13. Microsporum audouini. Hair from scalp in case of ringworm. X 800. Stain: Adamson's modification of Gram's method. The violet spheres are spores of the fungus on the surface of the hair
14. Naked-eye culture of Mycobacterium tuberculosis. (*See* fig. 10, Plate I)
15. Impression of minute colony of Bacillus anthracis. X about 20. Unstained. Note the "Medusa locks" arrangement of the filament of bacilli. The demonstration by Robert Koch in 1876 of the causal relation between anthrax (splenic fever) and a specific bacillus marks the beginning of modern bacteriology. (*See* fig. 11, Plate I)
16. Mycobacterium leprae in tissue. From subcutaneous nodule in case of leprosy. X 1,500. Stain: Carbol fuchsin, methylene blue

for example, a greater resistance to an antibiotic than the other cells, it has the advantage and will outgrow them if the antibiotic happens to be present in the environment. Soon the culture is composed of antibiotic-resistant individuals. The same effect is true of other properties; the environment tends to give certain mutants an advantage. If it does not, the mutant is often lost in the vast majority of other cells and is not recognized.

From 1942 much use has been made of radiations, such as ultraviolet light or X-rays, and of certain chemicals to induce mutations experimentally in bacteria. A gene mutation usually alters a biochemical reaction of the cell, and the mutant differs in one primary way from the nonmutant parent strain. It is not possible to specifically change any gene that one may wish, but the cells are exposed to the radiation or other mutagenic agent and then the treated population is "screened" by one method or another to detect the desired altered type. In this way bacterial populations have been obtained experimentally that are more resistant to chemical agents (penicillin, a sulfonamide, dyes, etc.), or to ultraviolet radiation, or to bacteriophage or other detrimental agents; the mutants may have different nutritive requirements; they may carry on certain aspects of cell metabolism through different channels than the nonmutant cells or exhibit a difference in any one of many other properties.

3. Rate of Multiplication.—Given suitable conditions for growth, the rate of asexual multiplication of bacteria is very rapid; it has been found that a cell divides every 20 or 30 minutes.

Assuming that conditions are conducive to a rate of one division every 30 minutes, a single individual cell will have produced 4 cells at the end of the first hour, 16 at the end of two hours and about 1,000,000 at the end of 15 hours. It can be calculated that these would occupy a space of one cubic millimetre. Such a mass of bacteria, easily visible to the naked eye, is called a colony, and it is no unusual thing in bacteriological practice to obtain colonies of this size as the result of one night's growth. Conditions for bacterial growth, fortunately for man's position in the world, never remain favourable for such unrestricted growth very long.

In order to produce any quantity of bacteria there must be an equivalent weight of suitable food material. There are other factors that influence the growth of bacteria. For instance, the by-products of bacterial activity, unless removed, militate against bacterial growth. It is very noticeable when cultivating bacteria in the laboratory upon plates of nutrient media; growth, which in the initial stages of incubation is so rapid that a colony may appear in 10 to 15 hours, gradually becomes less rapid and usually comes to a complete standstill after 30 to 36 hours. Many of the by-products of bacterial growth are acidic, and acids generally are unfavourable to bacterial multiplication.

V. CONDITIONS AFFECTING GROWTH OF BACTERIA

1. Food Requirements.—Bacteria must obtain from their environment all nutrient materials necessary for their metabolic processes and cell reproduction. The food must be in solution and must pass into the cell. In general, large molecules such as proteins and starches do not penetrate, but there is evidence of selectivity on the part of the cell wall or membranes with respect to penetration of smaller molecules. The food materials contain the elements carbon, hydrogen, oxygen, nitrogen, sulfur and phosphorus in varying degrees of complexity. Other important elements also are supplied: potassium, sodium, calcium, magnesium, manganese, iron, copper, cobalt and others. If the supply of even one essential substance is inadequate, metabolic activities and growth are limited. As with those of other living organisms, the foods essential for bacteria can be placed in four main groups: (1) sources of energy; (2) building materials for the cell; (3) accessory growth factors or vitamins; (4) inorganic salts. Water is also necessary.

Bacteria exhibit great diversity with respect to the particular chemical forms in which the elements can be utilized as nutrients. Certain bacteria, termed autotrophs, are able to make use of inorganic compounds, including carbon dioxide. Others, termed heterotrophs, require organic compounds (those derived from living organisms). The distinction between autotrophs and heterotrophs, though not as clear-cut as formerly believed, is nevertheless useful. Most bacteria, including the disease-producing species, are heterotrophs.

Autotrophs.—Among the autotrophs are a few bacteria that contain chlorophyll or a chlorophyll-like substance. These bacteria, like the algae and higher green plants, secure energy from sunlight. They obtain carbon from carbon dioxide, nitrogen commonly in the form of an ammonium salt, and other elements from inorganic compounds. From such simple substances their own cell protoplasm is formed.

Other autotrophic bacteria lack chlorophyll and are unable to cause photosynthesis. They secure carbon from carbon dioxide or carbonates and the other elements from inorganic compounds, like the previous group. They are remarkable in being able to derive energy from the oxidation of elements or very simple compounds. One group obtains energy from the oxidation of sulfur, another from the oxidation of ammonia to nitrites and a third from the oxidation of nitrites to nitrates.

The many differences in the metabolic activities of different bacteria are apparent when it is seen that a few bacteria that possess chlorophyll are not autotrophs but, on the contrary, use organic compounds as the source of hydrogen for reduction of carbon dioxide in photosynthesis.

Heterotrophs.—Heterotrophic bacteria derive energy from the oxidation of relatively complex organic food materials, such as sugars, other carbohydrates and fats. These substances also supply carbon for the building of new cell material. There are great differences among the various heterotrophic bacteria regarding the diversity of compounds each can utilize. Some, for example, are able to break down a wide variety of different sugars. Others can utilize only glucose or a few closely related sugars. A few are unable to utilize glucose and must rely on other organic compounds for carbon moieties and energy. The differences are due to different enzymic actions of the cells.

Nitrogen.—The same diversity is seen with respect to the requirement for and the utilization of nitrogenous compounds. The nitrogen needed for formation of new cells is supplied primarily by amino acids (the "building blocks" of protein) or other relatively simple compounds of nitrogen combined with carbon, hydrogen, and often oxygen. Some bacteria are able to synthesize (manufacture) all of the 20 or so amino acids needed for their cell protein, using inorganic nitrogen, such as in an ammonium salt, as the source of the nitrogen of the amino acids. A limited few are able to capture and fix nitrogen itself (see *Some Activities of Bacteria: In Soil: Nitrogen Fixation*, below). These bacteria are still classed as heterotrophs because other organic compounds are needed. In contrast, other heterotrophic bacteria lack the ability to synthesize one or more amino acids and must secure them preformed from the environment. The amino acids thus required vary from 1 to 12 or more, and often differ somewhat from the 8 to 10 required for human or rat nutrition.

Vitamins.—Vitamins that play an important part in bacterial metabolism are mostly the B vitamins: thiamine (vitamin B_1), riboflavin (vitamin B_2), niacin, biotin, pantothenic acid, vitamin B_6, pteroylglutamic acid (folic acid), and vitamin B_{12}. The roles played by these different vitamins in microbic metabolism are similar to their roles in higher forms of life and are necessary for the proper functioning of the cell. Great diversity also exists among different kinds of bacteria with respect to their ability to synthesize vitamins from simpler substances. Some bacteria—unlike man and animals—can synthesize all known vitamins used in their metabolic processes. In such cases the vitamins do not need to be supplied along with the food materials. Indeed, such bacteria are one of the important sources of vitamins in nature. Other bacteria are deficient in synthesizing ability and may be unable to synthesize one, two or half a dozen vitamins. Since these vitamins are required for the usual cell functions, they must be obtained from the environment. Under natural conditions this often occurs.

Laboratory Cultivation.—For cultivation of the usual heterotrophic bacteria in the laboratory, digests of protein (called pep-

tone) and an extract of meat are commonly used. Sometimes a sugar is added. These substances are dissolved in water to give 0.5% to 1.0% solutions. They supply a wide variety of both carbon- and nitrogen-containing organic foodstuffs, some vitamins and inorganic salts, including some metal ions needed only in trace amounts. For certain microorganisms, however, such a culture medium may be supplemented with certain vitamins or other compounds. Of the natural fluids available, milk supplies the nutrients needed by most bacteria and is an excellent culture medium. It must be realized that a deficiency of any one required substance, whether it is an amino acid, vitamin or metallic ion, is sufficient to limit or prevent cell metabolism and growth, even though all other requirements for growth have been met.

2. Temperature.—For every bacterium there are certain cardinal points of temperature. There is first the minimum point, below which growth is impossible. This varies with individuals, but for the majority it lies between 5° and 10° C.; some marine bacteria and certain soil types are active near 0° C., but they are exceptions. The optimum, depending largely on the usual habitat of the organism, is around 30° C. for soil organisms and about 37° C. for animal parasites. The maximum, above which no growth is possible, for many organisms lies between 38° C. and 48° C. Death of the organism as a rule occurs at a point about 10° or 15° higher than the maximum temperature for growth. The actual death temperature can only be considered in relation to time; a low temperature acting for a long time will produce the same effect as a high temperature applied for a short time. A thermal death point standard has been chosen arbitrarily by bacteriologists and represents the lowest temperature that, when applied for exactly ten minutes, will destroy every individual in a fluid suspension of the organism. Temperatures below the minimum prevent bacterial growth but there appears to be no equivalent thermal death point at low temperatures. It is known that typhoid and other disease germs survive quite a long inclusion in ice, and instances are known in which typhoid epidemics have been spread by ice cream. J. MacFadyen and S. Rowland found that organisms frozen in liquid air and even in liquid hydrogen at −252° C. were still capable of development when restored to normal incubation temperature.

Thermophilic Bacteria.—A few bacteria are unusual in that they are able to carry on active cell metabolism and multiply at 50° to 60° C. or even somewhat higher temperatures that would deactivate or kill other bacteria. The term thermophilic has been applied to these forms. Some thermophiles are active only at higher temperatures; others are active also at more ordinary temperatures, as 30° or 37°.

Thermophilic bacteria are sometimes responsible for the heating that occurs in haystacks or manure heaps. They occur also in hot springs. They do not belong to any one morphological group of bacteria; some are rod-shaped, others round or spiral. Some are not able to form spores. What peculiar property or attribute of the cell substance permits them to remain alive and active at high temperatures is not known.

3. Sterilization.—Methods of sterilization have to be chosen in full appreciation of the high resistance to heat of the bacterial spore cell. The ordinary cells are destroyed at temperatures of 50° to 60° C., hence a single boiling of a fluid or even pasteurization (application of heat of 63° C.) is sufficient to destroy them or most of them. The spores, however, must be subjected to very prolonged heating at these temperatures before they are destroyed; in order to produce sterility in a liquid in a reasonably short time, temperatures above 120° C., obtained by steam under pressure, are employed. Dry spores withstand even higher temperatures, but 160° C., maintained for 60 minutes, will usually destroy them.

4. Moisture.—Experiments have shown that bacteria will not grow in soil when the water content is 2% to 3%, but bacteria become active at 5% to 10% and reach their optimum, depending on the character of the soil, at 25% to 40%.

The importance of moisture for bacterial growth will be seen clearly if it is realized that bacteria have no mouth parts and that all their food must be imbibed in a soluble form by the process of diffusion through the cell wall; without sufficient moisture, therefore, the inflow of food and the outflow of excreta becomes impossible. Microorganisms vary considerably in their resistance to drying, and some die much more quickly than others. Practical use is made of drying, or desiccation, in many ways: in dehydration of foods, for example, and in other industries where the product is subject to microbic spoilage. By extracting sufficient water from the product, microbic cell metabolism is stopped and spoilage prevented. The cells are not always killed, however, and if the moisture content is allowed to rise sufficiently spoilage may soon occur. The point at which this happens varies with the product and many other conditions.

In general, molds are able to develop under conditions of somewhat lower moisture content than are the bacteria; consequently molds are often the most serious offenders in spoilage of flour, grain, textiles and other products.

5. Oxygen.—Bacteria of various kinds exhibit wide differences in their relation to oxygen of the air. Some need oxygen for respiration and cannot grow unless it is provided. These are known as aerobes. Others grow only in the absence of free oxygen and are unable to use it in their respiration; they are called anaerobes. Still others can grow under either condition and are termed facultative. Anaerobes, in spite of their peculiar requirement, are common in nature and are encountered in decomposing organic matter, in soil and in the mud of pond bottoms. Often they are able to grow in association with aerobes. It has been shown that the relative proportion of oxidizing and reducing conditions, as expressed by what is termed the oxidation-reduction potential, is important in the growth of anaerobes. If sufficient amounts of reducing substances, such as ascorbic acid (vitamin C), cysteine, or other such agents are present, even strict anaerobes may be grown in open tubes in the laboratory exposed to air. Spore-forming anaerobes have been especially troublesome in the canning of food. If the product is heated insufficiently, a few spores may survive the processing. Later they germinate and the cells multiply in the food product since the amount of oxygen is lowered inside the heated container; spoilage results. These bacteria are often harmless, but occasionally *Clostridium botulinum* is encountered. This anaerobe, the cause of botulism, forms a toxin that is extremely poisonous to man and many animals when taken by mouth.

6. Light.—Bacteria die rapidly if thin layers of them are exposed to direct sunlight, as for instance on the surface of an agar plate. Some organisms survive under these conditions for only 10 or 15 minutes. Sunlight is regarded as one of the most powerful destroyers of pathogenic germs. The part of sunlight that possesses the lethal effect is that at the ultraviolet end of the spectrum. Ultraviolet rays with a wave length of around 2,600 Å are especially effective. Some artificial sources of ultraviolet light provide a greater concentration of rays within this range than does sunlight. Most nonspore-forming bacteria, or those that have not gone into the spore stage, are killed by a few minutes of exposure if the source of the light is relatively close, within a foot or two. Spores are most resistant. While ultraviolet light is effective and useful if properly controlled it has certain limitations of application although many extravagant statements of its effectiveness have been made.

7. Reaction of the Culture Medium.—The reaction of the culture medium, that is, the amount of free acid or free alkali present in it, is of the greatest importance for bacterial development. A culture medium that is neither acid nor alkaline is said to be neutral and is best adapted to the growth of many kinds of bacteria. There are numerous organisms that are favoured in their growth by a faintly acid medium and others that prefer the medium to be slightly alkaline. The reaction is commonly expressed in terms of the reciprocal of the hydrogen ion concentration, using the symbol pH. A value of pH 7.0 represents the neutral point; lower figures, such as 6.0, 5.5, etc., represent increasing acidity; higher figures, such as 7.6, 8.0 and so on, represent increasing alkalinity. Most species of microorganisms are able to grow within a range of pH 6.0 to 8.0. Some bacteria and many yeasts and molds are able to grow in environments as

acid as pH 3.5 to 4.5, a few at a pH of 2.0 to 3.0.

8. Antiseptics and Disinfectants.—Many substances inhibit metabolic activity and multiplication of microorganisms. Some produce this effect without killing, others kill within short periods of time. A distinction between these effects is not always clear; a high dilution of a substance may merely inhibit while a more concentrated strength kills in a short time. Mercuric chloride, the alcohols, carbolic acid and many phenolic compounds are well known as disinfectants. Several other groups of substances have found increasing usefulness: the surface active agents, sulfonamide drugs and antibiotics. The antibiotics are substances produced by microorganisms that inhibit the growth of other microorganisms (see *Bacteriology in Industry*, below). The chemical constitution of some of the antibiotics is not known.

There are great differences in the effectiveness of antiseptics and disinfectants; consequently, they are used for many purposes: as preservatives in a variety of products, or as killing agents when applied to open wounds or internally. A number of factors either speed or retard the process of disinfection. The more important of them are the concentration of the disinfecting substance, the length of action time, the number and kinds of bacteria present, temperature, surface tension and other characteristics of the surrounding environment.

The spores of bacteria are usually much more resistant to disinfection than are the cells without spores. But even among nonspore-forming bacteria there are differences in resistance to different disinfectants; thus a staphylococcus from boils or abscesses may survive a treatment with a disinfectant that would kill the typhoid bacillus. However, toward another substance the typhoid bacillus might be somewhat more resistant than the staphylococcus. Stated another way, the differences in resistance seen in different bacteria with respect to one disinfectant cannot always be carried over and applied to another disinfectant, particularly one of a different chemical group and with a different mode of action. The compounds that are most useful in treating infections are not necessarily those that produce the speediest killing. In some cases the potency is relatively low but the substance is of value because it restrains the activities of bacteria and at the same time is not especially toxic to man and animals in the amounts usually needed.

VI. BACTERIA IN AIR AND WATER

Bacteria have existed from very early periods, as is shown by their presence in fossils; the researches of B. Renault and P. van Tieghem have shown that large numbers of bacteria existed in Carboniferous and Devonian times. In modern times they are universally present in still ponds and ditches, in running streams and rivers, in the sea, especially in drains, rubbish and manure heaps, in the soil and wherever organic matter is allowed to stand for a short time. Any liquid (blood, urine, milk, beer, etc.) containing organic matter or any solid foodstuff (meat, bread, potatoes, etc.) allowed to stand exposed to the air soon swarms with bacteria if sufficient moisture is present and the temperature is not abnormally cold. Though they occur in the air all the world over their distribution is by no means equal in all parts. As might be conjectured, they are most numerous in the air of cities, but even there the number of living bacteria is not so great as one would expect considering the enormous number of dust particles. Every mote in the air doubtless carries its quantum of bacteria, but the conditions of rapid drying and the exposure to ultraviolet light are responsible for the death of some of the organisms that are raised by the wind from the earth's surface. The air of the country is relatively free from bacteria as compared with that of the towns. The atmosphere over the ocean becomes more and more free from microscopic organisms as the distance from land increases.

The possible transmission of disease-producing bacteria through the air has attracted attention from the earliest days of bacteriology, particularly in the case of the bacteria causing respiratory infections that are found in the mouth and nose. It is known that in coughing or sneezing many small droplets of moisture are ejected out of the mouth or nose in the form of a fine spray. Bacteria on the mucous membrane are also expelled and may float in the air for a time before settling.

While many of these bacteria are killed by drying within a relatively short time (since most disease-producing bacteria are not able to form spores), it is quite possible for some of them to reach other persons in instances where a short route and a short space of time are involved. Thus, it appears that air-borne infection is mostly limited to the immediate environment of the sick person or the carrier.

The bacterial flora of water is quite varied. Each stream and pond receives a generous contribution of microscopic life from nearby soil. Many of the microorganisms thus carried into water supplies are unable to multiply and often gradually die. At times, however, sufficient organic matter and other food materials are present to permit some limited multiplication of bacteria in natural waters. In the mud and decomposing vegetative material of pond bottoms large numbers of bacteria from the intestinal tracts of man and animals may find their way into water supplies in populated areas. Many from this last source are harmless types, but occasionally disease-producing bacteria from the intestine also gain access to a water supply. Typhoid bacilli, dysentery bacilli and the cholera vibrio may be transmitted from one person to another by such means.

VII. SOME ACTIVITIES OF BACTERIA

1. In Milk and Dairy Products.—Without bacteria or other microorganisms milk undergoes little detectable change and may be kept in its original state almost indefinitely. Different kinds of bacteria and related microscopic forms produce different effects when they gain access to milk and multiply in it. Some attack principally the milk protein and break it down with the accompaniment of decomposition odours; others attack principally the milk sugar and produce acid from it, often curdling the milk; still others may curdle the milk through the agency of an enzyme secreted by the cells. In unheated milk, acid-forming bacteria (such as *Streptococcus lactis* or various species of *Lactobacillus*) frequently gain the upper hand and the milk sours without decomposing. For some purposes such an effect is desirable, and lactic-acid-producing bacteria may be added purposely to induce a controlled fermentation.

Many disease-producing bacteria are able to multiply readily in milk if the temperature is sufficiently high. Since the metabolic activities and multiplication of bacteria are slowed or stopped at lower temperatures, refrigeration of milk is important. Occasionally disease-producing bacteria may invade milk from the cow, the milk handler or by other means, in spite of all precautions. To protect against this mischance the milk is pasteurized by heating at a temperature of 143° to 145° F. for 30 minutes or else at a higher temperature such as 160° F. for a shorter time. These methods destroy disease-producing microorganisms that might be present and at the same time kill a large percentage of harmless microorganisms.

Bacteria play a part in the preparation of many milk products. In buttermaking, milk cultures of certain bacteria are mixed with the cream or are worked into the butter to add flavour. In the making of cheese, coagulation of the milk protein at times is brought about by acid produced by acid-forming bacteria. Since the numbers and kinds of bacteria present are of prime importance, cultures of a desired kind, called "starters," often are added to control the flavour and appearance of the product as well as to form acid.

Many different kinds of cheeses may be made by varying the conditions of manufacture and assuring a certain sequence of events in proper order under controlled conditions. Activity of some microorganisms is encouraged while that of others is suppressed. Lactic-acid-forming bacteria, propionic-acid-forming bacteria, types that digest fats or proteins and molds all play a part in the various steps in the process.

2. In Soil.—Many different kinds of bacteria, molds and other microorganisms are numerous in fertile soils and play an outstanding role in determining the composition of the soil and its

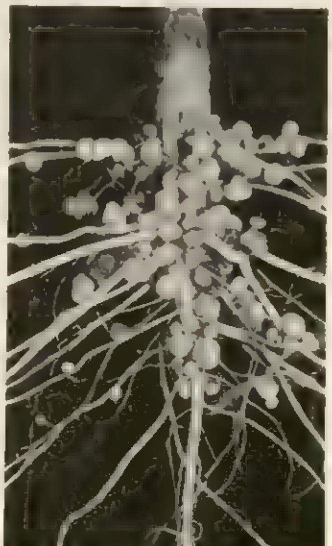
productivity for plant life. Most of this microbic population is found in the top few inches of soil. The usual range in numbers is from about 1,000,000 to 50,000,000 bacteria per gram (about $\frac{1}{30}$ oz.) of soil with lesser numbers of molds and other forms. However, much smaller as well as larger numbers may be encountered. These soil microorganisms are quite diverse as to kinds and metabolic activities. There is a complicated interplay of effects of one upon another. Some exert a restraining effect upon others while some assist the growth of others. In addition, their activities are governed by a wide variety of conditions, some of which are more favourable to certain types; *i.e.*, the amount of organic matter, inorganic salts, moisture, temperature, acidity or alkalinity and the supply of oxygen. The changes that go on in the presence of a mixed flora of this sort are exceedingly complicated; nevertheless it has been possible to assign definite roles to some of the microorganisms by means of pure culture studies carried on in the laboratory. Some of these activities are of the utmost importance to the existence of higher plants, animals and man.

Nitrogen Fixation.—One of the most striking processes is that of nitrogen fixation. This is the process by which the element nitrogen, a gas that composes roughly 80% of the air, is combined with other substances and made available to various forms of life in the form of nitrogenous compounds. Very few types of living cells are able to accomplish this combination because nitrogen is relatively unreactive chemically. Artificially, that is, by strictly chemical methods in contrast with the biological method, high temperatures and high pressures are necessary to cause nitrogen to combine with either hydrogen or oxygen.

In contrast, certain bacteria are able by means of little-understood catalysts in the cells to bring about the combination of nitrogen and hydrogen at ordinary temperatures and pressures. The first recognizable product of this process is ammonia (NH_3) or an ammonium compound. Once this stage is reached many reactions can occur. The simple nitrogen compound resulting from the first stage in fixation is combined with carbon compounds by bacteria or plants to make various organic nitrogenous compounds. In one way or another, sometimes only after a number of changes, the nitrogen compound becomes available as plant food. Thus the soil is enriched in nitrogenous compounds through the nitrogen fixation. Since many field crops deplete the supply of nitrogenous compounds in soil, it is evident that nitrogen fixation counteracts this loss by "capturing" nitrogen from the air.

The bacteria making this unique contribution to the natural economy are some species belonging to each of the following groups: *Rhizobium, Azotobacter, Clostridium* and another that is unusual in containing a pigment akin to the chlorophyll of green plants. In addition, one or more of the blue-green algae are known to be able to fix nitrogen.

Rhizobium exhibits an unusual relationship with leguminous plants (alfalfa, clover, pea, soybean, lupine and others). The bacteria form small nodules on the roots of these plants and it is there that the process of nitrogen fixation occurs. Different species of *Rhizobium* show a considerable degree of specificity for one or another of the leguminous plants. For this reason the farmer who seeks to enrich soil through the addition to it of these bacteria must take into account the kind of legume to be grown and add the appropriate kind of *Rhizobium*. Efficient fixation of nitrogen by *Rhizobium* under field conditions occurs only if this requirement is fulfilled.



BY COURTESY OF THE NITRAGIN COMPANY

FIG. 5.—SOYBEAN ROOTS SHOWING BACTERIA-CONTAINING NODULES IN WHICH NITROGEN FIXATION OCCURS

The remaining nitrogen-fixing microorganisms are free-living forms and fix nitrogen independently of a plant relationship. Several species of *Azotobacter* are important nitrogen fixers. The practical importance of the other nitrogen-fixing bacteria is not well established. In the laboratory under appropriate conditions they fix nitrogen effectively, but their practical importance in soil is not entirely clear.

Decomposition of Organic Matter.—Another important bacterial action in the soil is the decomposition of organic matter. Many large molecules containing carbon and nitrogen are added to the soil through the death of plants and animals; these large molecules occur as cellulose, starches, lignins, fats, proteins and others. A number of soil microorganisms possess enzymes that are capable of breaking down these molecules to much simpler substances. These changes are complex, and there is a complicated interplay of many factors in determining the final result, but it is known that many of the large numbers of microorganisms in soil play a part. One of the products resulting from the decomposition of protein and other nitrogenous organic compounds is ammonia. The process by which it is formed is known as ammonification. Thus the nitrogen at one time locked in large protein molecules is once again converted to a simple form, ammonia or an ammonium salt, that is quite reactive chemically and readily undergoes further changes.

The oxidation of ammonia to nitrite and of nitrite to nitrate is termed nitrification. Relatively few kinds of bacteria bring about this change, but those that do are widely distributed in large numbers in most soils. *Nitrosomonas* and *Nitrosococcus* accomplish the first stage of the oxidation process by forming nitrite; *Nitrobacter* oxidizes nitrite to nitrate.

It is apparent that microorganisms play important parts in many of the changes undergone by nitrogenous compounds in soil. Equally important changes are brought about in nonnitrogenous compounds. Large molecules composed of carbon, hydrogen and oxygen, such as cellulose and starches, are broken down by some of the soil microorganisms to simpler fragments. These simpler compounds, in turn, are more readily assimilated by various forms of life and used as sources of energy and as building material for cellular substance.

Other changes are brought about with respect to sulfur, phosphorus, iron and inorganic compounds. Sulfur occurs to some extent in the protein of the cells of dead plants, animals, and microorganisms, and in protein decomposition products. It is found also in nature in the form of sulfates, hydrogen sulfide and the element sulfur itself. A good number of the soil microorganisms take an active part in one or another of the transformations of sulfur. Some produce hydrogen sulfide from the sulfur of organic compounds. Others oxidize the hydrogen sulfide to sulfur and then to sulfates, an important source of sulfur for green plants. One rather striking group of sulfur-oxidizing bacteria, *Thiobacillus*, oxidizes sulfur to sulfuric acid, which under most conditions is soon converted to sulfate. Many of the changes in phosphorus, iron and other inorganic compounds are also brought about by the varied microbic population of the soil.

3. Sewage Disposal.—Microorganisms play an important part in the treatment of sewage. As a rule large numbers of bacteria are present in sewage; some of them are of intestinal origin, others are from soil, air and, in some cases, from industrial wastes. Many of these bacteria are able to decompose the organic matter present in sewage. A main objective in any method of sewage treatment is to remove or decompose the organic material to a final product that is stable chemically and not subject to further decomposition. The changes by which this is accomplished are essentially similar to those occurring in natural decay, but they are carried out under controlled conditions. Another prime objective is the destruction of any disease-producing bacteria that may be present. The processes that go on and the final products formed depend in large measure upon the conditions under which digestion occurs and the degree of aeration.

In preliminary settling tanks a considerable proportion of the solid matter settles out as sludge. In deep tanks anaerobic bacteria play the predominant part. Proteins, cellulose and other

large molecules are broken down to simpler end products. Here the breakdown is rapid but only partial. Part of the suspended organic material is liquefied and gases are formed, but some of the products are objectionable and are subject to further changes. If the product is aerated, as in a trickling filter or in the activated sludge process, aerobic species of bacteria predominate, organic matter is decomposed and more rapid and complete oxidation occurs. The products of ammonification are oxidized to nitrites and nitrates, the sulfides to sulfates, and in general more stable and less objectionable end products are formed. The over-all process here has been a pronounced breakdown and digestion of the organic matter originally present with the formation of soluble and on the whole quite simple and stable end products that can be emptied into a nearby body of water or otherwise disposed of without undergoing further decomposition. The final product may be chlorinated before discharge into a neighbouring body of water to destroy any disease-producing bacteria that may have survived the treatment process.

VIII. BACTERIOLOGY IN INDUSTRY

This subject may be divided into two parts, one dealing with the application of microbic activities that yield desirable products, the other concerned with the destruction caused by bacteria and related microorganisms in industrial undertakings. The division, of course, is not always clear-cut and some problems of economic importance do not fit exactly in either category. Most of the following discussion deals with the use of bacteria to produce desirable products.

Careful attention to minute details of practice in these industrial processes is imperative. Such details include concentration of the nutrient media (particularly of sugar and salt), degree of acidity, amount of aeration and temperature control.

1. Baking and Production of Baker's Yeast.—The fermentation that takes place during the raising of dough is usually induced by the addition of suitable types of yeast—baker's yeast. This shortens the time of dough raising and prevents other miscellaneous microscopic forms in the flour from taking part in the process. The large-scale production of yeast for use in baking calls for scrupulous attention to many details to insure the maximum production of a satisfactory yeast crop. Selected strains of *Saccharomyces cerevisiae* are employed.

Nutrient materials consist of appropriate substances to supply nitrogenous and carbon compounds, salts and vitamins; mashed grains, molasses and ammonium lactate are commonly used. Since the objective is a large yeast crop the material is aerated, and little alcohol remains in the final product.

2. Bacterial Decomposition of Pectin.—The bacterial activities that cause decomposition of the pectinous middle lamellae of plant tissues have long been exploited for the retting of fibre plants. The best-known example is that of flax retting. Many attempts have been made to substitute the use of vats, controlled conditions and known cultures of bacteria for the old custom of relying upon chance contamination with appropriate microorganisms in a pond or slow-flowing stream where the bundles of plant material are immersed. The old procedures are still used, however, in many parts of the world.

Enzymes capable of softening the pectin layer of the plant are possessed by relatively few bacteria and related microorganisms. *Clostridium felsineum* (*Bacillus felsineus*) and several bacteria related to *Clostridium butyricum* are important pectin-dissolving bacteria. Enzymes capable of breaking down pectin have also found considerable use for the pretreatment of fruit juices as a means of clarification. Such commercial pectolytic enzymes are usually obtained from molds, especially various species and strains of *Penicillium* and *Aspergillus*.

3. Decomposition of Starch and Sugars.—In addition to brewing and wine making, there are many other processes in which starch- and sugar-decomposing enzymes of bacteria, yeasts and molds can be used in producing industrially important products. (Most of the products listed below also can be produced commercially by synthetic processes.)

Ethanol.—Ethanol (ethyl alcohol) is produced for many industrial purposes and by several different processes. Most ethanol produced for human consumption is a product of sugar fermentation by yeast, of which the most commonly used is *Saccharomyces cerevisiae*. The starting material varies; it may be molasses or starchy materials such as corn, wheat or potato mashes. Since starch is not attacked directly by the yeast it is necessary first to convert the starch to sugar by cooking under pressure, followed by the use of enzymes. Yeast is added, fermentation takes place and the alcohol is recovered by distillation.

The details of treatment, types of containers and other items vary. Another source of commercial ethyl alcohol is sulfite liquor, a waste product in papermaking that contains some sugar. After removal or neutralization of certain detrimental substances resulting from earlier treatments, yeast is added and the fermentation ensues.

Glycerol.—The production of glycerol (glycerin) by yeast through the breakdown of sugars is based on the fact that sodium sulfite and certain other alkaline salts, when added to a fermenting sugar solution, interfere with the normal alcoholic fermentation and cause glycerol to accumulate at the expense of alcohol and carbon dioxide. Yields of 25% of glycerin, on the basis of the sugar fermented, may be obtained.

Acetone-Butanol Fermentation.—A number of bacteria produce closely associated fermentations that yield acetone, ethanol and butanol (butyl alcohol) as the chief end products. *Clostridium acetobutylicum* (formerly termed *Bacillus granulobacter pectinovorum*) is usually employed. Molasses or starchy material such as ground corn meal is most commonly used in the United States as a starting material. From this there is produced about 60% butanol, 30% acetone and 5% ethanol. Here again, attention to many details and careful control of the process are important.

During World War I the fermentation was used chiefly for acetone production. Later, a demand arose for butanol in the manufacture of paints and lacquers and this became the principal product of industrial importance. Many other fermentation processes involving the breakdown of starchy materials, cellulose and related substances have been described. Various end products may be obtained depending upon the microorganism used and the conditions employed in the process.

Acetic-Acid (Vinegar) Fermentation.—In the production of vinegar from sugary solutions, such as apple juice or other fruit juices, two main fermentations are involved. One is brought about by yeast that converts the sugar to ethyl alcohol and carbon dioxide; a second fermentation oxidizes the alcohol to acetic acid. The latter is caused by *Acetobacter aceti*, *Acetobacter xylinum* and related species, all commonly referred to as acetic-acid bacteria. The organisms grow on the top of the mixture in a thick jellylike layer called mother of vinegar. Various methods of making vinegar differ with respect to the type and size of the vats, methods of aeration, etc. In some instances alcohol rather than sugar is used as the starting material to facilitate the process.

Citric Acid.—The conversion of sugars to citric acid can be performed by certain fungi, notably by species of *Aspergillus*. High sugar concentration—about 15%—and adjustment to a fairly high acidity facilitate citric-acid production with concurrent production of only small amounts of oxalic acid.

Gluconic Acid.—Gluconic acid, an oxidation product of glucose, is produced by a number of the molds and by some bacteria. Certain strains of *Penicillium chrysogenum* and *Aspergillus niger* have found favour as producers of high yields of the product. Good yields of gluconic acid may be obtained by submerged growths and aeration. Gluconic acid is converted to the calcium, sodium or other salts for various medicinal or industrial uses.

Lactic Acid.—By employing certain bacteria known as lactic-acid bacteria, sugar solutions can be made to undergo another

type of fermentation that results in the accumulation of lactic acid. This fermentation was exploited industrially from the middle of the 19th century, but the introduction of modern bacteriological methods and the use of pure cultures improved the yield and reduced the occurrence of undesirable secondary fermentations. Yields of 85% to 90% on the basis of the sugar fermented may be obtained. *Lactobacillus delbrueckii*, *L. casei*, *L. plantarum* and several related species, as well as *Streptococcus lactis*, are the bacteria chiefly used.

During the fermentation a calcium salt is added to neutralize the acidity that would otherwise limit metabolic activity of the bacteria and lead to incomplete fermentation. Lactic acid is recovered as calcium lactate.

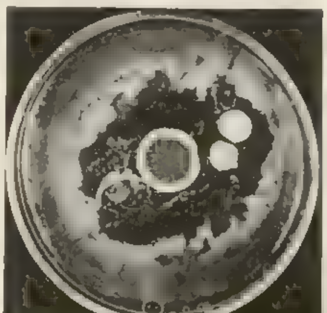
4. Enzyme Preparations.—Aside from the end products of fermentation, the catalytic agents, or enzymes, in the cells of microorganisms are themselves desirable for some industrial uses. Most microorganisms produce a variety of enzymes, and some species have been found to be convenient sources of them. Enzymes that break down proteins and starches (proteases and amylases) have been prepared from some of the fungi, such as *Aspergillus oryzae*, and from bacteria.

The microorganism is grown in a suitable culture environment with nutritive materials, some of which serve as substrate for the enzyme desired. When maximum enzyme activity has developed the material is harvested by extracting the enzyme with water or an appropriate solvent. This crude concentrate may be purified to some extent depending upon its intended use.

5. Vitamin Production.—Most microorganisms are capable of synthesizing a number of the B-complex vitamins that are needed by man and animals. It is probable that microorganisms constitute an important source of the vitamins in nature. In some instances microorganisms have been used as sources of vitamins, particularly in some of the industrial fermentations where large masses of microorganisms and liquor remain after a fermentation product has been recovered. The vitamin thus represents an additional product of value that may be secured. Many yeasts contain considerable quantities of vitamin B_1 (thiamine). Several processes for vitamin B_2 (riboflavin) production have been patented, based on the use of one or another of the yeasts such as *Eremothecium* or *Candida*. *Clostrium acetobutylicum* synthesizes riboflavin, and material from the acetone-butanol fermentation contains considerable amounts of this vitamin. *Streptomyces griseus*, which is used for production of the antibiotic, streptomycin, gives a good yield of vitamin B_{12}. Yeasts contain ergosterol, a substance yielding vitamin D when irradiated. There can be little doubt that many other microorganisms might be utilized for the production of one or another of the vitamins.

6. Antibiotics.—The antibiotics are chemical substances produced by living microorganisms and are capable of inhibiting the growth of other microorganisms. Many microorganisms produce antibiotic substances, but the most important sources have been some of the filamentous fungi, particularly certain penicillia and aspergilli, the actinomycetes—filamentous branching forms classed with the bacteria—and the bacteria proper.

The phenomenon of antibiosis, the inhibitive effect of one organism upon another, is an old one and was observed in the early days of microbiology. It attracted only transient interest for years because many of the earlier antibiotic preparations were quite toxic to higher forms of life and therefore impractical to use. In 1929 Alexander Fleming in England called attention to penicillin—so named because it is derived from a mold of the *Penicillium* group.



BY COURTESY OF MERCK & CO., INC.

FIG. 6.—THREE LARGE COLONIES OF PENICILLIUM NOTATUM. DARK ZONE AROUND THE COLONIES REPRESENTS BACTERIAL INHIBITION, THE PHENOMENON THAT LED TO THE DISCOVERY OF PENICILLIN

This substance was effective against certain bacteria and at the same time much less toxic than earlier antibiotic preparations. Many investigators tested literally thousands of molds, actinomycetes and bacteria for their ability to produce substances effective against one or another of the disease-producing bacteria or filterable viruses. By the early 1960s about 500 antibiotic substances had been given names. Some of them were possibly duplications; others might prove to have no practical value; but a few had shown considerable promise and had taken a place among the most potent of weapons for combating bacterial infection, largely replacing the sulfa drugs.

The antibiotics are prepared by growing the organism on a large scale, often in large tanks or vats but sometimes in shallow layers of nutrient solution. The details of cultivation vary considerably, depending upon the organism and the substance sought, but in each case exact attention to detail is highly important in obtaining maximum yield. Then the material is subjected to different processes to separate the antibiotic from other products of microbic growth; these processes are at times quite involved and expensive.

Many of the antibiotics have been subjected to chemical analysis and in some instances the exact chemical structure is known, penicillin, for example. Most of them have turned out to be molecules too big or too complicated to be prepared commercially by purely synthetic chemical processes, so that microorganisms are still relied upon for the most part for their production. The question of just how antibiotics bring about their beneficial effects in combating microbic invasion of man and animals had been only partially answered by the early 1960s. (*See* ANTIBIOTICS.)

7. Destruction by Bacteria in Industrial Processes.—In contrast with the many benefits obtained from the controlled utilization of bacteria and related microorganisms in industrial processes is the large amount of damage that may result from their uncontrolled activity. It is important and sometimes very necessary to arrest or prevent their activity. In the textile industries, for instance, much damage is caused through the destruction and mildewing of fibres and fabrics. In the meat industry one of the prime problems has been reduction of the number of bacteria and other microorganisms together with prevention of their growth in meat products. In the sugar industry the cane or beet juice is often changed (inverted) by bacteria to a less desirable type of sugar in which crystallization is rendered difficult.

Another problem in this industry is the formation from sugar by bacteria of gummy materials that interfere with the manufacturing processes.

In the wood industries serious losses occur through the action of some of the fungi. In dairying, in dairy manufacturing and in many other industries serious economic loss is caused by the activities of bacteria.

(1954), both of the foregoing references contain lists of antibiotics; L. B. Jensen, *Microbiology of Meats*, 3rd ed. (1954); F. W. Tanner, *The Microbiology of Foods*, 2nd ed. (1944).

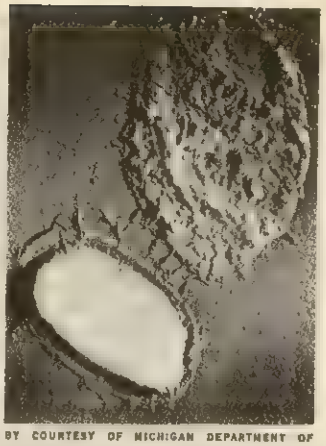
IX. VIRUSES ATTACKING BACTERIA (BACTERIOPHAGES)

A bacteriophage is an agent that causes transmissible lysis (disintegration and dissolution) of bacteria. This phenomenon was noted by F. W. Twort in 1915 and by F. H. d'Hérelle in 1917. The latter coined the term bacteriophage (sometimes abbreviated to phage) to indicate an agent that destroys bacteria. Bacteriophages are believed to be viruses. (*See* VIRUSES: *Bacterial Viruses* [*Bacteriophages*].)

1. Infection Process.—The effect of bacteriophage on a test-tube culture of susceptible bacteria is quite striking, and the result may be seen without the aid of a microscope. Ordinarily, as bacteria multiply in a test tube in a solution of nutrient materials the liquid becomes very turbid because of the newly formed mass of bacterial cells. If a drop of bacteriophage is added to the culture at an early stage in development, the turbidity disappears and the liquid becomes quite clear. On microscopic examination few, if any, bacteria can be seen. Within a few hours many mil-

lion bacteria have been destroyed. If a cleared or lysed culture is passed through a very fine filter, the bacteriophage goes through but the whole or intact bacterial cells do not. If a very small amount of filtered material containing bacteriophage is added to another young culture of the same bacterium, lysis of the cells again occurs.

This process can be repeated indefinitely. Since the lysis can be transmitted in series with undiminished vigour it is evident that the lytic agent, bacteriophage, is reproduced during the process. When a mixture of bacteria and bacteriophage is viewed through the microscope during the process of lysis, the cells of the bacteria are usually seen first to swell and then suddenly to disappear, with perhaps only a shadow or vague suggestion of the cell remaining for a short time. With each destruction of a cell many phage particles are released and are then free to make contact with other cells, where the process is repeated in a short time. The phage multiplies in numbers at the expense of the bacteria. Thus, as bacterial cells are lysed the bacteriophage population increases, eventually reaching a high figure such as 100,000,000 to 1,000,000,000 or more phage particles in a millilitre (about $\frac{3}{100}$ oz., or $\frac{1}{5}$ tsp.).



BY COURTESY OF MICHIGAN DEPARTMENT OF HEALTH

FIG. 7.—ELECTRON MICROGRAPH OF BACTERIA BEING ATTACKED BY BACTERIAL VIRUS (BACTERIOPHAGE): (BOTTOM) BACTERIUM APPARENTLY STILL HEALTHY; (TOP) BACTERIUM IN LAST STAGES OF DESTRUCTION. BACTERIOPHAGE PARTICLES ARE THE MINUTE, PADDLE-SHAPED OBJECTS SEEN AT THE CELL SURFACE OF THE BACTERIA

The same phenomenon occurs when bacteria are grown on the surface of a nutrient jelly instead of in a liquid. If a drop of bacteriophage is applied to a film of susceptible bacteria growing on such a surface, lysis of the bacterial cells occurs and a clear area results. The area may be large or small depending upon the extent of the original application of phage. If a high dilution with only a few phage particles rather widely distributed is brought in contact with a similar surface film of growing bacteria, small areas in the film of bacteria are cleared of cells and show up as moth-eaten spots, termed plaques.

2. Nature of Bacteriophages.—For many years a lively discussion centred upon the nature of bacteriophages. It became generally agreed, however, that bacteriophages are viruses and that their fundamental characteristics are similar to those of other viruses that cause diseases of man, animals or plants. Thus it appears that bacteria, including many that produce disease in higher forms of life, are themselves subject to disease caused by still smaller microorganisms, the viruses.

Phages are not ordinarily visible with the usual light microscopes. With the development of the electron microscope it became possible to obtain an accurate idea of their appearance, which can be seen clearly at magnifications of 15,000 × to 30,000 ×. Many phages are spherical or oval; others tend to be somewhat cubical in shape; and some have a hexagonal-shaped "head" portion with a slender "tail" attached, giving a tadpolelike appearance. In size the different bacteriophages range from about $\frac{4}{10,000,000}$ in. to $\frac{8}{1,000,000}$ in. in diameter. Where a tail is present it may be as much as $\frac{5}{1,000,000}$ in. long in the case of some of the larger phages.

The conditions under which phages develop are limited. Like most of the viruses, which multiply either exclusively or for the most part within the cells of the host, there is an intimate relation between the bacteriophage and the host cell. The phage does not propagate by itself in any of the nutrient solutions used for test-tube cultivation of bacteria.

For reproduction the phage ordinarily requires the presence of young, living and actively metabolizing bacterial cells. Phage does not propagate in the absence of susceptible bacteria, nor does it multiply on dead cells; however, it may be adsorbed on the surface of the latter.

Bacteriophages exhibit a considerable degree of specificity with respect to the kind of bacteria attacked, and different kinds or races of phage have been recognized on this basis. In some cases a single species of bacterium is affected; at times the relationship is even more specific in that only a single strain, or a few strains, of a species are lysed. In other instances the range of activity is broader and several species may be affected by the same phage. Where this occurs it often happens that the species belong to a closely related group.

Phage activity with cell lysis seems to be limited to the cells of bacteria and a few related microorganisms. There appear to be no recorded instances of comparable injury to the cells of higher forms—man, animals or plants. Sometimes bacteriophage may be carried by resistant bacteria, termed lysogenic strains. Thus a culture of the colon bacillus, a common inhabitant of the intestinal tract of man, may carry a bacteriophage capable of lysing the dysentery bacillus. The colon bacillus is not affected by the phage for the dysentery bacillus, but when contact with the appropriate dysentery bacillus is made under favourable conditions, propagation of the dysentery phage takes place and lysis of dysentery bacilli occurs.

If events are followed closely after a bacteriophage is brought into contact with susceptible bacterial cells, it is evident that subsequent developments occur in several stages. First, phage particles are adsorbed on the surface of the bacterial cell. Environmental conditions also play a part, and the contact may not occur in the absence of certain important organic compounds and inorganic salts.

Next, the phage or a part of it penetrates the bacterial cell. This is followed usually by multiplication of the phage within the cell and then by a process in which phage units change to some extent or become "mature." The phage, or the deoxyribonucleic acid of the phage, takes over genetic control of the host cell and new phage units are produced.

The last stage is that of lysis of the bacterial cell. The cell breaks down and phage particles are liberated, usually about 100 to 200 or more of them from one cell. This often occurs within 20 to 40 minutes after the phage was adsorbed on the bacterial cell; the process of new phage formation evidently is a speedy one. The liberated particles are adsorbed to other cells and the process previously described is repeated until practically all of the bacteria have been destroyed. At times, one or more cells resist the lytic action of the phage. Later these resistant cells may multiply in the presence of the lysed material, thus producing a variant or mutant culture of the bacterium that is resistant to the phage.

3. Metabolism, Resistance, Occurrence.—The metabolic activity of bacteriophages is evidently quite limited. They appear incapable of carrying out many of the energy-yielding processes and other metabolic reactions that independent single living cells must perform in order to exist. Presumably they benefit from the processes carried on in the bacterial cell, supposedly appropriating for their own use some of the energy and materials from the cellular processes at the time of multiplication. It is difficult to separate the metabolic processes of such intracellular parasites from those of the host cells, but there is evidence that the bacterial cell is not simply divided into many smaller units, each of which becomes a bacteriophage particle. Characteristic phage substance is synthesized within the bacterial cell and this process involves for the most part the combination of relatively small molecules, a large portion of which are drawn from the environment. When a bacteriophage, purified to free it from extraneous materials as far as possible, is subjected to chemical analysis it is found to consist largely of protein and deoxyribonucleic acid. The latter substance is a characteristic constituent of the nuclei of the cells of many forms of life. It is present in unusually high proportion in bacteriophage. This is in agreement with the often-expressed idea that phages contain a bare minimum of substances found in most cells—some nuclear materials and not much else. Polysaccharide is absent, or present

in only small amounts, in the several phages that have been subjected to analysis.

Bacteriophages are antigenic; *i.e.*, when introduced into the animal body they stimulate the production by the animal of immune substances (antibodies) specific for the bacteriophage. This is analogous in a general way to the response on the part of the body to typhoid or smallpox vaccination when immune substances specific for the disease organisms are formed. The antibodies formed in animal tissues in response to bacteriophage have the property of neutralizing activity of the phage when mixed with phage and susceptible bacteria. They are specific for particular types of phage; *i.e.*, antibodies for one type of phage do not affect those of another type. Bacteriophages are subject to variation or to mutationlike changes that remain constant through subsequent intracellular periods of propagation.

These changes may involve characteristics such as the size and type of plaques formed, resistance to heat, resistance to a dye or changes in the specificity of phage for different bacteria.

Resistance of bacteriophages to disinfectants and to physical agents, such as light and high temperatures, is not notably different from that of the respective nonspore-forming bacterial cells with which they are associated. Bacteriophages are inactivated by exposure to X-rays and ultraviolet light. Bacteriophages may retain their ability to lyse susceptible bacteria for a year or more when held at refrigerator temperatures. They may be encountered in nature; sewage, feces, contaminated water and pus from wounds are some of the other sources in which they are found. They are usually obtained by first passing the material through a fine filter to remove bacteria and then adding some of the filtered material to a young actively growing culture of the species of bacterium against which a phage is desired. Its presence is made evident by lysis of the bacteria.

A number of attempts have been made to exploit for practical purposes the unique properties of bacteriophages. Obviously any agent that multiplies at the expense of bacteria and destroys them while at the same time perpetuating itself might, theoretically at least, be of great value. The possibility of using appropriate races of bacteriophages as agents for treatment of human and animal diseases caused by bacteria was one of the first items to receive attention. This was strongly championed by d'Hérelle in the decade or so following the discovery of bacteriophage activity and was tried by many others in various parts of the world. Races of bacteriophages specific for one or another of the bacteria causing human or animal disease were applied in various ways: taken by mouth in the case of intestinal infection (such as typhoid or cholera), injected into boils or abscesses, introduced into the urinary bladder and even injected into the blood stream in cases of invasion of the blood by bacteria such as the streptococcus. However, results on the whole were definitely disappointing and there is little evidence that bacteriophages assist or play a part in recovery from infectious disease. Apparently the phages do not make contact with the bacterial cells, or the environment is such as to delay or prevent adsorption of phage onto the cells. Obviously such conditions are quite different from those of the laboratory in which lysis occurs so readily. The high hopes at one time entertained for such a practical use of bacteriophages were not fulfilled.

Phages have also been studied from certain other aspects, particularly for elucidation of some fundamental characteristics of viruses. The ease with which they may be handled in the laboratory, propagated in bacterial cultures, obtained in concentrated and relatively pure form all combine to make them the instrument of choice for attempts to unravel some of the mysteries of viruses as a group. This is particularly true of studies on the source of food materials.

With the use of radioactive isotopes of carbon, nitrogen and phosphorus it has been possible to ascertain with a considerable degree of accuracy what food substances come from smaller molecules in solution in the environment of the host cell and to learn what may be derived by the virus from the substance of the host cell that is parasitized.

Correlated with this aspect of virus nutrition is the problem of how the virus forms new units like itself when conditions for multiplication are appropriate. The method by which the virus penetrates a host cell and the sequence of events immediately following this event are also fundamental questions that may be answered by the use of bacteriophages and bacteria as experimental tools. Some idea of these processes, it is hoped, may assist in clearing up some of the uncertainties regarding virus infections in general. Thus, bacteriophages are of outstanding scientific interest.

(S. A. Kr.)

BACTRIA (BACTRIANA) is the ancient name of the country lying between the Hindu Kush (Paropamisus) mountains and the Amu Darya (Oxus) river, with its capital Bactra, also called Bactra-Zariaspa (probably Balkh [Wazirabad], ancient Vahlika). In Islamic times the area was known as Tukharistan, after the Tukharians who settled there in the 1st century B.C., and was usually differentiated from the northern plain of the Amu Darya, but anciently it may well have included both plains. The main features of Bactria are its extreme flatness and severe climate. The greater part of the region is a waste of barren clay flats or sand. In places the soil would be rich agriculturally if irrigation were available; elsewhere it is heavily impregnated with salts. (For other physical features and climate *see* AFGHANISTAN.) The modern population includes Tajiks, Uzbeks and Turkmens and an element of recently settled Afghans (Pathans).

Archaeologically Bactria has great potentialities. There is a profusion of mounds and abandoned water channels that testify to its ancient prosperity. Leaving aside the finds of Stone Age remains in the alluvial gravels at Balkh and in cave deposits at Haibak, the recent settlement begins with Iron Age deposits at Balkh and Khulm. These correspond to the earliest settlements at Samarkand, Merv and Kobadian in Soviet territory and may date from the second quarter of the 1st millennium B.C. They appear to be the relics of an Eastern-Iranian-speaking people who settled there at that time, and should belong to the society in which Zoroaster taught. If so then the references in the Avesta to "Baxdis beautiful with banners" must refer to this first settlement at Balkh. (*See* ZOROASTRIANISM.)

Bactria enters history with the Achaemenids. It appears along with Sogdiana, Parthia and Aria in the Achaemenid satrapal lists, and Herodotus further describes the Bactrian soldiers who fought in the army of Darius and mentions the tribute paid by the 12th satrapy. Probably Bactria was first subdued by Cyrus and remained an Achaemenid province for two centuries. When Alexander the Great had defeated Darius III, the Bactrian satrap Bessus tried to organize resistance in the east, but Bactria was soon overcome. Along with the other Asian satrapies Bactria passed under the rule of Seleucus Nicator upon the death of Alexander.

Both Alexander and his successors established Greek colonies or cities in their territories, and the great fortifications at Alexandria-Bactra (?Balkh) and Alexandria of the Oxus (?Termez) should date from this time. In the second half of the 3rd century B.C. either Diodotus (*q.v.*), the Seleucid satrap of Bactria, or his son of the same name threw off the imperial yoke and founded an independent kingdom. Antiochus III the Great defeated their successor, the usurper Euthydemus (*q.v.*), but nevertheless continued to recognize his independence, providing as he did a buffer against the unruly nomads of the north. Euthydemus' son Demetrius I (*see* DEMETRIUS) extended Greek rule in several directions, and in the next decades Antimachus and Demetrius II advanced into the Hindu Kush and thence into northwestern India where they established the Indo-Greek branch of the kingdom. The extent of the Greek domains was somewhat curtailed by the vigorous campaigns of the Parthian Mithradates I, who *c.* 160 B.C., during the reign of Eucratides (*q.v.*), even invaded Bactria itself. Some time before 125 B.C. Greek rule

north of the Hindu Kush was suddenly challenged by the advance of the Yüeh-chih hordes into Sogdiana and the lands beyond the Amu Darya. By 125 B.C. the Greeks were their tributaries, and soon afterward the Yüeh-chih occupied Bactria. Greek rule may have continued for a decade in the valleys of Badakhshan.

It was formerly thought that the influence of the Bactrian Greek kingdom was far reaching and that whole new fields of art (*e.g.*, the Gandhara style of northwestern India) owed their existence to it. This view must be modified. Except for their remarkable coinage (*see* NUMISMATICS: *Asiatic Coins: India*) the material remains of the Bactrian Greeks differ little from those of their non-Greek neighbours, and there is no evidence that they imported works of art from their homeland in any quantity. From the start the cities were as much Asian as Greek, and the same is probably true of their ruling groups. On the other hand the Greek script continued to be used in Bactria and central Asia for many centuries after the end of Greek rule, and Greek influence may also be detected in the Sanskrit drama. The influence so strongly present in the Gandhara art style relates to Roman-Parthian contacts at the beginning of the Christian era.

The Yüeh-chih tribes were possibly an Iranian people. They certainly included the Tukharians, who later gave their name to Bactria. During the 1st century B.C. they settled in the area and appear to have rapidly absorbed elements of Parthian-Hellenistic culture. Thence in the 1st century A.D. they extended their rule into northwestern India. This movement is associated with a group known as the Kushans, who reached the zenith of their power under the emperor Kanishka (*q.v.*). In the latter half of the 4th century there appear to have been fresh invasions, bringing the Little Kushans under Kidara and soon after the Hunas (Chionites) including the Hephthalites (*q.v.*). These two latter are thought to have been non-Iranian, possibly Mongol. The Hephthalites settled in Bactria and thence for two centuries warred with the Sassanians. In 565 the western Turks overthrew them and ruled in Bactria until the mid-7th century when Arab armies carried Islam into Tukharistan. For later history of the area *see* AFGHANISTAN.

BADAGA, the most numerous of the peoples of the Nilgiri hills of Madras state in the south of India. They have increased very rapidly, from less than 20,000 in 1871 to about 85,000 by the early 1960s. Their language is a Dravidian dialect closely akin to Kannada (Kanarese, *q.v.*) as spoken in Mysore state to the north of the Nilgiris. The name Badaga means "northerner" and it is clear that they came into the Nilgiris from the north, perhaps impelled by economic or political pressures. The time of their migration was after the founding of the Lingayat sect in the 12th century, because some of them apparently came as Lingayats. It was before the first recorded observation of them, by a Catholic missionary in 1602, when they were well established and maintaining symbiotic relations with the other Nilgiri peoples.

The Badagas are divided into six endogamous groups which were ranked in ritual order. The two highest were vegetarians; the lowest provided servants for the other five. Their traditional religion and economy depended on goods and services supplied by the Nilgiri peoples—Kota, Toda (*qq.v.*), and Kurumba.

Badagas generally have taken to education and have vigorously advanced their community. In addition to grain, they now grow large crops of potatoes and vegetables. Concomitantly, most have altered their traditional religious and social practices. Improved agriculture, local and national policies, high-caste Hindu tradition—these matters now engross a good many Badagas. In all, the Badagas are one of those indigenous groups who have turned their circumstances in the 20th century to success for their community.

(D. G. M.)

BADAJOZ, the largest province in Spain, which with Cáceres, forms the region of Extremadura (*q.v.*). Area 8,362 sq.mi. (21,658 sq.km.), representing 4.3% of the total area of the country. Pop. (1960) 834,370. The climate is characterized by the extreme length of its summers, which are dry and hot, when the temperature often exceeds 40° C. (104° F.), sometimes the highest in Spain. The province is almost entirely flat, but rises in the south and southwest near the Sierra Morena, and in the north joins the foothills of the mountains of Toledo. It is crossed from east to west by the Guadiana (*q.v.*) river, of which the most important tributary is the Zujar. One of the most typical areas of the central plain is the Tierra de Barros, the largest cereal, wine and oil-producing region of Extremadura. Its main centre is Almendralejo. Another region is the Vegas Altas y Bajas del Guadiana which extends on both sides of the river and contains the historic town of Mérida (*q.v.*). Serena is a wool-producing area and a centre for the merino breed of sheep. Another area is that known as Siberia Extremena from its arid and extreme climate.

In 1952 the Spanish government promoted a scheme known as the Plan Badajoz which considerably raised the standard of living, productivity and agriculture and intensified development and industrialization in the province. Irrigation was undertaken using the waters of the Guadiana and the Zujar. Six dams were constructed (Cijara, Puerto Peña, Orellana, Zujar, Alange and Montijo) with a total capacity of 3,245,000,000 cu.m. (*c.* 114,600,000,000 cu.ft.) which permits about 1,000 cu.m. (about 35,314 cu.ft.) of water to be used each year for irrigation. The Instituto Nacional de Colonización created new towns and established thousands of settlers to whom grants of land were made. Industrially the Plan Badajoz provided for the establishment of new industries based on agriculture: flour, vegetable preserving, oil and cotton. Electrification was also increased, and communications improved. The province is crossed by the Madrid-Badajoz, Cáceres-Seville, and Zafra-Jerez de los Caballeros railway lines.

BADAJOZ, the provincial capital, overlooks the Guadiana from a slight eminence, crowned by the ruins of a Moorish castle. A bastioned wall with moat and outworks and forts on the surrounding heights gives an appearance of great strength. The river, which flows between the castle hill and the fort of San Cristóbal, is crossed by a granite bridge, built in 1596 and rebuilt 1833. The aspect of Badajoz recalls its stormy history; even the cathedral (1234–84) resembles a fortress with massive embattled walls. Badajoz was the birthplace of Manuel Godoy, duke of Alcudia (1767–1851), and of the painter Luis Morales "the divine" (1509–86). Two pictures by Morales, unfortunately retouched in modern times, are in the cathedral. The city enjoys a considerable transit trade with Portugal; its principal industries are the manufacture of foodstuffs of various kinds, alcoholic and other drinks, basket work, blankets and wax. Pop. (1960 est.) 110,580.

History.—The most outstanding episodes in the history of Badajoz occurred during the Peninsular War. French troops under Marshal Nicolas Jean de Dieu Soult, duke of Dalmatia, attacked and took the town in March 1811. In May the English under Viscount Beresford tried to recover it but had to retire in the face of strong resistance by the French garrison. The duke of Wellington, with the Spanish generals Joaquín Blake, Francisco Javier de Castaños and Francisco López Ballesteros, won the battle of Albuera nearby and decided to put Badajoz to the siege again, but Wellington's attacks were ineffective and the siege was raised. The following year, 1812, Wellington, already master of Ciudad Rodrigo, returned to Badajoz, where the siege recommenced on March 16. The French troops under General Philippon resisted strongly, but eventually the English were able to take the fortress of San Vicente and enter the town. The French fled and then surrendered. The English troops put the captured town to the sack for three days. (*See* PENINSULAR WAR.) In the Spanish Civil War the nationalists of General Franco captured Badajoz on Aug. 14, 1936.

BADAKHSHAN, including the Wakhan panhandle, is a province on the northeast frontier of Afghanistan. Area 16,000 sq.mi. Pop. (1962 est.) 316,574. It is bounded on the north by the southern bank of the Amu Darya (Oxus) or its headstream the Panj (Ab-i-Pandj). On the west it is bounded by a line which crosses the Turkistan plains southward from Chah-i-Ab near the Amu Darya until it touches the eastern water divide of the Kunduz river and then runs south along the Khwaja Muhammad range until it strikes the Hindu Kush. The southern boundary is carried along the crest of the Hindu Kush as far as the Dorah pass (14,941 ft.). The Dorah connects Zebak and Ishkashim, at the bend of the Amu Darya, with the Lutku valley leading to Chitral. From the Dorah eastward the crest of the Hindu Kush again becomes the boundary until it effects a junction with the Muztagh and Sarikol ranges, which shut off China from the Soviet Union and Kashmir. Skirting the head of the Tafdumbash Pamir, it merges into the Pamir boundary, and turns westward later following the course of the Pamir river and the Panj to near Chah-i-Ab. Before 1873 the small states of Rushan and Shugnan extended to the left bank of the Amu Darya and the province of Darwaz extended to the right bank. Now, however, the two extensions are exchanged and the river throughout is the boundary between Soviet and Afghan territory; the political boundaries of those provinces and of Wakhan are no longer coincident with their geographical limits.

The Kokcha river traverses Badakhshan from southeast to northwest and, with the Kunduz, drains all the northern slopes of the Hindu Kush west of the Dorah pass. Some of its sources are near Zebak, close to the great bend of the Amu Darya northward, so that it cuts off all the mountainous area included within that bend from the rest of Badakhshan. Its chief affluent, the Minjan, is a considerable stream where it approaches the Hindu Kush close under the Dorah. Like the Kunduz, it probably drains the northern slopes of the Hindu Kush by deep lateral valleys, more or less parallel to the crest, reaching westward toward the Khawak pass (11,650 ft.). From the Amu Darya (1,000 ft.) to Faizabad (6,083 ft.) and Zebak (8,500 ft.) the course of the Kokcha offers a highroad across Badakhshan; between Zebak and Ishkashim, at the Amu Darya bend, there is a comparatively low pass of 9,500 ft.; and from Ishkashim by the Panj, through the Pamirs, is the continuation of what was once probably a much-traversed trade route connecting Afghan Turkistan with Kashgar and China. North of the Kokcha, within the Amu Darya bend, is the mountainous district of Darwaz, of which the physiography belongs to the Pamir type rather than to that of the Hindu Kush.

A very remarkable meridional range extends for 100 mi. northward from the Hindu Kush (across this range lies the route from Zebak to Ishkashim), which determines the bend of the Amu Darya northward from Ishkashim, and narrows the valley of that river into a trough as far as the next bend westward at Kala Wamar. The western slopes of this range drain to the Amu Darya northwestward, by the Kokcha and the Ragh, or else they twist their streams into the Shiwa, which runs due north across Darwaz. There again the main routes which traverse the country follow the rivers closely.

The more important wild animals of Badakhshan include a large wild sheep (*Ovis poli*), foxes, wolves, jackals, bears, boars, deer and leopards; among birds, there are partridges, pheasants, ravens, jays, sparrows, larks and a famous breed of hawks.

Badakhshan proper is inhabited primarily by Tajiks or Tadzhiks (*q.v.*) and some who speak the Persian and Turkic languages and profess the orthodox doctrines of the Islamic law adopted by the Sunnite sect, while the mountainous districts to the east are inhabited by Tajiks, professing the Shi'ite creed and speaking distinct dialects in different districts.

The chief urban centres are Faizabad (*q.v.*), the capital, Rustak, Zebak, Kishm and Jurm.

Under cultivation are about 320 sq.mi. of which about half are irrigated. The main crops are wheat, barley, maize, rice, pulses, alfalfa and cotton. Vines and fruit trees are common in gardens. The principal domestic animal is the yak. There are also large flocks of sheep, cows, goats, ponies, dogs and Bactrian camels. Forestry and mining are not important industries; however, the lapis lazuli (*q.v.*) mines on the upper Jurm river are still in production. (J. P. C. N. H.)

History.—The name Badakhshan first appears in the Chinese writers of the 7th and 8th centuries A.D., Hsüan Tsang and T'ang-shu. In the 5th century A.D. it had formed part of Tukharistan ruled by the Haytal or Hephthalites (*q.v.*). They were displaced in the 6th century by the Turks and in the 7th century by the Arabs. Of the details of Muslim penetration, nothing is known. After falling first under the Ghorids of Bamian, in the second half of the 12th century, and then under the Khwarizmshah, at the beginning of the 13th, Badakhshan escaped the full consequences of Genghis Khan's destruction of the Khwarazmian empire in the 1220s. For two centuries it remained under a local dynasty claiming descent from Alexander the Great. In 1466–67, however, it came under the rule of the Timurids. Sulaiman, nephew of the Mogul Babur (*q.v.*), ruled the country from *c.* 1530 to 1575. In 1584 the Uzbek Abd-Allah Khan conquered it, and although there were Timurid attempts to regain it, Badakhshan became part of the loosely confederated Uzbek empire in 1669. It remained under the local Uzbek dynasty of the Mirs until 1822 when it was overrun by Murad Beg, the Kataghan Uzbek of Kunduz. After intermittent dynastic struggles under his descendants, in 1873 the area south of the Oxus (Amu Darya) river and west of the Panj was annexed by Afghanistan. By 1891–92 the Russians had penetrated the whole of eastern Pamir. In 1895, an agreement between Britain and Russia allotted Badakhshan proper to Afghanistan, and the territories of western Pamir, north and east of the Panj to the principality of Bukhara (*q.v.*), under Russian protection. After the Revolution of 1918, this Pamir region became the Gorno-Badakhshan Autonomous *oblast* (*q.v.*), part of the Tadzhik Soviet Socialist Republic, U.S.S.R.

See article "Badakhshan," *Encyclopaedia of Islam*, vol. i, 2nd ed. (1958). (P. H.)

BADALONA, a town of northeastern Spain, in the province of Barcelona and Catalonia is situated on the outskirts of Barcelona city along the shores of the Mediterranean, at the mouth of the Besós river. Its geographical position gives it a temperate climate both in summer and winter. Its beach, extending for about 3½ mi., is much frequented. Pop. (1960) 92,257. Although an industrial suburb of Barcelona, Badalona has a character of its own derived from a history of more than 2,000 years. During the Roman occupation it was the important Baetulo that was founded before Barcelona. Numerous relics from these times are preserved in the town museum. The ancient buildings include the Gothic monastery of San Jerónimo de la Murtra; the *cartuja* (Carthusian monastery) of Montalegre; the plateresque palace of Pinós; and the Pallaresa tower where the emperor Charles V stayed before leaving for the conquest of Tunis. Badalona has a variety of industries including the manufacture of chemicals, metals, glass, spirits, perfume and textiles. (S. A. VA.)

BADDELEY, ROBERT (*c.* 1732–1794), English actor, chiefly remembered for his will, is said to have been a cook to the actor Samuel Foote. Later, as a valet he acquired a familiarity with foreign languages and manners that made him especially successful in "broken English" parts. In 1761, described as "of Drury Lane theatre," he was seen at the theatre in Smock alley, Dublin, as Gomez in Dryden's *Spanish Friar*. Two years later he was a regular member of the Drury Lane company in London. He remained at this theatre and the Haymarket until his death on Nov. 20, 1794. He wore scarlet and gold livery as a King's Servant, being the last actor to do so.

Baddeley was the original Moses in *The School for Scandal*. In his will he bequeathed property to found a home for infirm actors and also money to provide wine and cake in the green room of Drury Lane theatre on Twelfth-night. The ceremony of the Baddeley cake remained a regular institution.

His wife, SOPHIA BADDELEY (1745–1786), was born in London,

the daughter of a sergeant-trumpeter named Valentine Snow. At the age of 18 she ran away with Baddeley, then acting at Drury Lane, and appeared there on April 27, 1765, as Ophelia.

Her extravagance and profligacy led him to leave her, and after a career as actress, singer and courtesan, she died in Edinburgh in July 1786.

See Elizabeth Steele, *Memoirs of Mistress Sophia Baddeley*, 6 vol. (1781).

BADEN, the southwesternmost part of Germany, forming the western part of the *Land* Baden-Württemberg (*q.v.* for geographical detail) in the German Federal Republic. Baden is bounded on the west by the Rhine, separating it from France and from the Palatinate, on the north by Hesse and by part of Bavaria, on the east by Württemberg and on the south by Switzerland.

HISTORY

The plains of Baden show traces of human settlement from the Stone Age onward. Inhabited by a Celtic population from the 4th to the 2nd century B.C., with centres at Breisach, at Zarten (near Freiburg) and at Ladenburg (on the Neckar) and occupied subsequently by Germans, the country was conquered in the 1st century A.D. by the Romans (*see* AGRI DECUMATES), who developed its economy, strengthened its defenses and early united it with their province of Germania Superior west of the Rhine. The spas (Ger. *Bäder*) of Baden-Baden and Badenweiler prospered under the Romans, as archaeological evidence shows. The Romans, however, were displaced by the Alamanni (*q.v.*), who invaded the area in the middle of the 3rd century and divided it between petty kings until in the 5th century a tribal or "stem" duchy began to emerge. The victory of Clovis over the Alamanni in 496 won the northern part of the country (up to the Oos and Murg rivers) for the Franks, but the south, at first under the protection of the Gothic king Theodoric, maintained a degree of independence until 748, when the Franks acquired it also.

The Franks, with the help of Irish missionaries, established Christianity in the place of Alamannic paganism. The monastic foundations of Säckingen, Schuttern and Ettenheimmünster date from the 7th century, those of Reichenau, Schwarzach, Gengenbach and St. Trudpert from the 8th. The Franks also set up countships instead of the old *Gaue* and tribal divisions, but on the decline of the Carolingian dynasty this system was weakened by the rise of a landowning class of ecclesiastical and secular magnates who acquired grants of crown lands and immunities from the authority of the counts. Some of the counts moreover sought to make themselves independent of royal control by uniting other countships to their own and by assuming new rights. The house of Zähringen was the major dynasty to rise by this process in southern Germany.

The Dukes and the First Margraves.—First recorded as counts of Breisgau in the 10th century, the Zähringer in the 11th and 12th centuries built up a ducal state which extended from the Black forest over much of Switzerland and Upper Burgundy and might have changed the course of history in southern Germany had not the line of dukes of Zähringen become extinct on the death of Berthold V in 1218. In 1061, however, Hermann I (d. 1074), the elder son of the duke Berthold I, had been invested with the mark or margraviate of Verona in Italy, and subsequently the margravial title had been transferred from Verona to the family seat at Baden. Less ambitious than the dukes, the Zähringer margraves were to form a more lasting power.

The rise of the margraves began with their acquiring rights as counts in Breisgau in the south and in Ufgau, near Baden-Baden, in the north. Their northern holding was strengthened by the addition of Pforzheim, Ettlingen and Durlach in the 13th century and consolidated as a territorial state by Bernhard I (1364–1431), but its further development was to some extent restricted by that of the Palatinate on its frontier. Jacob I, however, margrave from 1431 to 1453, established himself at Hunsrück on the western side of the Rhine in 1437 and acquired a condominium over the lordships of Lahr and Mahlberg in middle Baden in 1442, thus effecting a junction with the family's southern possessions. Separated from the northern margraviate since the 12th century, these southern possessions comprised the countships of Breisgau (part of which was alienated in 1218) and the lordships of Hachberg and Sausenberg, with Rötteln added in 1310 and Badenweiler in 1444. The extinction of the southern branch of the Zähringer in 1503 enabled Christopher I (d. 1527), margrave from 1475 to 1515, to unite the family possessions.

Christopher, who by acquiring Rodemachern as a fief from Luxembourg in 1492 had further strengthened his position west of the Rhine, now controlled a territory extending along the east bank of the Rhine from the gates of Basel to Graben south of Philippsburg (apart from some minor ecclesiastical and secular lordships). He organized it efficiently under a central administration, and Baden might thus have won a dominating position in the basin of the upper Rhine if the state had not subsequently been partitioned among the Zähringer. After a threefold distribution in 1515, the lands were finally divided in 1535 between two margraviates, Baden-Baden and Baden-Durlach.

Baden-Baden and Baden-Durlach.—The margraviate of Baden-Baden comprised, together with the districts west of the Rhine, the original family possessions in the Rhine basin from Bühl to Ettlingen with the condominium of Lahr and Mahlberg; everything else went to Baden-Durlach. For a short time both margraviates were Protestant, but Baden-Baden was brought back to Catholicism in the 1570s. As the two lines moreover became rivals dynastically, Baden was soon overshadowed as a power by neighbouring German states and was left helpless in the face of French expansion across the Rhine in the 17th century. The country was terribly devastated in the wars of this period; in 1689 the towns and citadels of Pforzheim, Durlach and Baden were completely destroyed. Louis William (called "Türkenlouis"), margrave of Baden-Baden from 1677 to 1707, distinguished himself as a commander in the imperial army, first against the Turks in the battle of Slankamen (1691), then against the French. It was he who built the palace of Rastatt as his residence. Charles William, margrave of Baden-Durlach from 1709 to 1738, likewise moved his residence—from Durlach to his newly founded Karlsruhe (*q.v.*).

Charles Frederick.—Under Charles William's grandson and successor Charles Frederick (*q.v.*), margrave of Baden-Durlach from 1738 to 1811 and of Baden-Baden also from 1771 (when the other line of margraves became extinct), the country enjoyed a long period of happiness and prosperity. Then the outbreak of the French Revolutionary Wars made the margrave's position difficult. His country was too open to attack by the French for him to remain long in the alliance against them. Having lost his possessions west of the Rhine, he was obliged to sign the treaty of Paris in 1796, which made him a satellite of France but also proposed compensations for his losses. Subsequent treaties in fact gave him such compensation that the margraviate was enlarged to four or five times its former size. Baden received, in 1803, not only parts of the bishoprics of Constance, Basel, Strasbourg and Speyer as well as Lahr, Lichtenau, Willstätt and several abbatial lands and imperial cities, but also the greater part of the Palatinate east of the Rhine, with Mannheim and Heidelberg; in 1805, part of Breisgau, Ortenau, Mainau and Constance itself; and, in 1806, Heitersheim, Fürstenberg, Leiningen, Wertheim, Klettgau, Bonndorf and the cantons of the knights of the empire. In 1803, accordingly, Baden was made an electorate of the Holy Roman empire and in 1806 it became a grand duchy.

The Grand Duchy.—Consolidated by a central administration, the grand duchy of Baden was recognized by the congress of Vienna in 1815 as a sovereign member of the German confederation. The granting of a constitution in 1818 made Baden one of the first German states to introduce the parliamentary system, and the deliberations of the *Landtag* were echoed throughout Germany even when reaction against the system was strongest. Under Leopold, grand duke from 1830 to 1852, the administration introduced more reforms, but these did not check the progress of radicalism, and the revolutionary movement of 1848 was particularly violent in Baden when Friedrich Hecker and Gustav von Struve raised volunteer troops to set up a republic. This rising was suppressed, but in 1849, when the army mutinied and a revolutionary government was set up, Prussian forces had to restore the grand ducal

administration. Frederick I, grand duke from 1852 to 1907, was the son-in-law of the future German emperor William I and favoured the "Little German" solution of the German question in the form of a close union with Prussia. Though circumstances made him take the Austrian side in the Seven Weeks' War (1866), after it he allied Baden with Prussia and took a leading part in the founding of the German empire. His internal policy, like Charles Frederick's, was characterized by legislative activity, concern for his people's welfare and encouragement of the arts and sciences. The last grand duke was Frederick II, who ruled from 1907 to his abdication at the close of World War I, in 1918.

Later History.—Baden was governed from 1919 to 1933 as a state of the German Reich, with its own state president, and then, under the Nazi regime from 1933, by a *Gauleiter* and *Reichsstatthalter*. During the occupation by the Allies after World War II, it was divided into French and U.S. zones, their boundary drawn between Karlsruhe and Rastatt. Subsequently these two northern and southern zones became administrative districts of the *Land* Baden-Württemberg.

BADEN (Baden bei Wien), a spa in Lower Austria, 17 mi. S. of Vienna, lies at the east edge of the Wiener Wald and at the gateway to the Helenental, a woodland dale watered by the Schwechat. Pop. (1961) 22,484. It is famous for its 15 warm (73° to 96° F.), radioactive sulfur-chlorine springs, used in the treatment of rheumatic pains, gout, neuralgia and neuritis, which rise chiefly at the foot of the Kalvarienberg (1,250 ft.), a mass of dolomitic limestone. There is a notable Roman spring with supply pipes dating from the year A.D. 1, and two swimming pools filled with water from the Marienquelle (95° F.). In the old town, besides most of the baths, are the town hall and the Gothic parish church of St. Stephen, which resembles St. Stephen's cathedral in Vienna. Beethoven, Mozart, Schubert, Johann Strauss and other composers, and poets have lived at Baden, and memorials to them are to be seen in the town.

Baden shows evidence of continuous settlement since early times and appears to have maintained its present function through the ages. West of the old town lie several parks and the Rollet museum which is rich in local prehistoric and Roman remains.

BADEN, a town in the Swiss canton of Aargau, lies on the left bank of the Limmat, 1,272 ft. above sea level, 14 mi. (23 km.) N.W. by rail of Zürich. Pop. (1960) 13,949. The hot sulfur springs mentioned by Tacitus were fashionable in the 15th, 16th and 19th centuries and still attract great numbers of persons of all nationalities who suffer from rheumatic complaints. The spa quarter is approached from the old town by a boulevard. The old town is very picturesque with its steep and narrow streets, and its one surviving gateway; it is dominated on the west by the ruined castle of Stein, formerly a stronghold of the Habsburgs, and contains also the town hall with an old assembly chamber and the municipal library. To the northwest of the baths is a new industrial quarter with large electrical engineering works. One mile south of Baden, on the Limmat, is the famous Cistercian monastery of Wettingen (1227–1841) which has old painted glass in the cloisters and early 17th-century carved stalls in the choir of the church; the monks are now at Mehrerau near Bregenz. Six miles west of Baden is Brugg, on the Aar, and nearby are the remains of the Roman colony of Vindonissa (Windisch), and the monastery (founded 1310) of Königsfelden, formerly the burial place of the early Habsburgs.

In 1415 Baden (with the Aargau) was conquered by the Eight Swiss confederates whose bailiff inhabited the castle on the right bank of the Limmat which defended the ancient bridge. The delegates of the confederates met at Baden from 1427 to about 1712. The diet sat in the old town hall. Baden was the capital of the canton of Baden from 1798 to 1803, when the canton of Aargau was created.

BADEN-BADEN, a town and spa in the Black forest of Germany which after partition of the nation following World War II was located in the *Land* of Baden-Württemberg, German Federal Republic, lies on the bank of a narrow stream, the Oos. Pop. (1961) 40,029. It owes its importance to its thermal springs, which have been known from Roman times. The baths, built in the reign of Caracalla (A.D. 211–217) for the garrison of Strasbourg, are still visible. After the departure of the legions the town fell to ruins and reappeared only in the middle ages; its first margrave (1112) was Hermann II of Zähringen. The town was almost entirely destroyed in 1689 and did not revive for nearly a century. It was an asylum for numerous refugees from the French Revolution. The popularity of Baden-Baden as a watering place dates from 1808 but it reached its zenith under Napoleon III, when it was the resort of French society. There is a casino which attracts many players. Among the buildings are the Greek chapel; the Trinkhalle or Pump room; the Friedrichsbad (1869–77), a bathhouse for men only; the Kurhaus social rooms; the Stiftskirche, now the parish church, founded in the 7th century on the site of a heathen temple, destroyed in 1689, rebuilt in 1753 and restored under the grand duke Leopold in 1837; and the Neues Schloss, which was built under the margrave Christopher (1475–1527). It too was partly destroyed in 1689, but was restored and enlarged very soon afterward. It was the residence of the grand dukes of Baden and has subterranean chambers which date back to Roman times.

The famous waters, saline and radioactive, are used for both bathing and drinking, and are said to be efficacious in the relief of certain rheumatic and paralytic conditions. The establishments are open all year. The station, on the railway line joining Karlsruhe and Freiburg, is Baden-Oos (3 mi. away), and there is an airport, Karlsruhe-Baden-Baden, about the same distance to the northeast.

BADENI, KASIMIR FELIX, Graf (1846–1909), Austrian statesman who worked for a reconciliation of the conflicting national interests of the western half of the empire, was born in Surochów in Galicia on Oct. 14, 1846. After studying law at the University of Cracow, Badeni, one of the richest Galician landowners, entered the Galicia department of the ministry of the interior in 1866 and was appointed district commissioner first for the district of Zolkiew (1871), then for Rzeszow and eventually *Statthalter* in Cracow (1879). Retiring to his estates in 1886, he returned to the civil service in 1888 as *Statthalter* of Galicia. On Oct. 2, 1895, Badeni, on the recommendation of the military, was appointed first minister and minister of the interior for the western half of Austria-Hungary. His appointment occurred at a critical time. Tax reform, settlement of the German-Czech language problem and reform of the suffrage laws could no longer be postponed, and the Compromise (*Ausgleich*) with Hungary of 1867 was soon to come under its decennial review. Badeni's first measure was to end the state of emergency in Prague, which had been declared in 1893. He opposed all extreme nationalism such as that of the anti-Semite Karl Lueger (*q.v.*). On Badeni's advice the emperor Francis Joseph three times refused to confirm the election of Lueger as chief burgomaster of Vienna.

In May 1896 Badeni brought about a suffrage reform which added a fifth category of electors consisting of all men over 24 years old who paid at least five gulden in tax. His tax reforms passed no less easily, and it was only with the elections of March 1897 that the situation became threatening. The Young Czechs, the Croats and the Social Democrats benefited most from the new voting structure, and to conciliate the Young Czech party Badeni elevated Czech to the status of an administrative language in Bohemia and Moravia. This provoked intense opposition from the German minority parties, especially from Georg Schönerer's faction (to which Lueger belonged), and in June 1897 Badeni prorogued the *Reichsrat*. The *Reichsrat* had to be reconvened in September to review the Hungarian Compromise; but on Nov. 26 and 27, authorized by new standing orders (the Falkenhayn laws), Badeni had some of the brawling deputies expelled by the police. Demonstrations followed in the streets of Vienna. Lueger, whose

fourth election to the burgomastership had been confirmed by the emperor, demanded Badeni's resignation, with the warning that unless constitutional procedures were restored there might be revolution in the city. Badeni had in fact offered to resign immediately before the November session of the *Reichsrat*, and on Nov. 28 the emperor accepted his offer. Because of this change of mind the measures that had been designed to allay discord between the nationalities had the effect of exacerbating it, as rioting broke out in Prague in protest against Badeni's resignation and a state of emergency had to be proclaimed there.

Badeni resolutely attacked the problem of the nationalities and, although his reputation has suffered from partisan misappraisals, his fall marked a serious loss for Austria-Hungary. He died near Krasne in Galicia on July 9, 1909.

BADEN-POWELL, ROBERT STEPHENSON SMYTH BADEN-POWELL, 1ST BARON (1857–1941), founder of the Boy Scouts' movement, was born in London, the seventh son of Baden Powell, Savilian professor of geometry at Oxford, on Feb. 22, 1857. He joined the 13th Hussars in India in 1876 and began to develop scouting as a branch of army training; this led to special service in Africa in Ashanti (1895) and Matabeleland (1896) but he returned to India in 1897 to command the 5th Dragoon Guards. During the South African War (1899–1902) his defense of Mafeking for 217 days made him a national hero; he was promoted major general and later was deputed to raise and train the South African constabulary. Baden-Powell became inspector general of cavalry in 1903. Finding that his book *Aids to Scouting* (1899) was being used for training boys, he ran a trial camp at Brownsea island, Dorset, in 1907 and published an outline scheme; Boy Scout troops (typically 20 to 40 boys) sprang up all over the country and *Scouting for Boys* was published the next year. Baden-Powell, promoted lieutenant general in 1907, left the army in 1910 to give all his time to the Boy Scouts. In the same year, the Girl Guides were founded. Both movements spread rapidly and Baden-Powell, acclaimed chief scout at the first international scout jamboree in 1920, toured the world several times to review scouts and guides, remaining active until his 80th year.

Baden-Powell was made a baronet in 1922, a baron in 1929 and was appointed to the Order of Merit in 1937. He married Olave St. Clair Soames in 1912; both she and his sister Agnes (d. 1945) did much to promote the Girl Guide movement. Baden-Powell died at Nyeri in Kenya on Jan. 8, 1941. *See* also BOY SCOUTS; GIRL GUIDES; GIRL SCOUTS.

BADEN-WÜRTTEMBERG, a *Land* in the German Federal Republic, was established in 1952 after a popular referendum held in Dec. 1951 which indicated the desire of the inhabitants to merge the three postwar *Länder* of Württemberg-Baden, Württemberg-Hohenzollern and South Baden into one state under a single constitution and prime minister. It lies in the southwest between the frontier with France on the Rhine to the west and the *Land* of Bavaria to the east. Area 35,750 sq.km. (13,803 sq.mi.).

Physical Geography.—The *Land* embraces five major physical divisions: the Upper Rhine plain, the Black forest, the Neckar lowland, the Swabian Jura and the Danube plateau.

The Rhine flood plain from Basel to Karlsruhe is wide and wet and is mainly under waterlogged pasture (*Ried*). Low sandy terraces with pine woods cover most of it. The foothills of the Black forest are fertile and intensively cultivated on minute holdings. There the trees are mainly oak and beech and elm. The Black forest (*q.v.*) is a highland penetrated by many short valleys but with no easy through routes. The lower altitudes are clothed in beechwoods, but upper levels have spruce forest or open pastures on the southern summits. The highland passes northward to the Kraichgau, a rolling limestone upland that is predominantly cultivated.

The Neckar (*q.v.*) river drains a great V-shaped lowland widening from the south between the Black forest and the Swabian Jura. There are three types of country: (1) Lowlands, developed on horizontal limestones and frequently covered with fine loam soils, border the west of the V at the foot of the Black forest (*Gaue*). The bare limestone is the realm of scrub and rough pasture, but the loam soils are covered with treeless expanses of arable land and large compact villages. (2) A belt of wooded, sandstone hills with west- and north-facing scarps stretches through the middle of the basin. (3) A zone of clay plains (Lias) lies between the sandstone hills and the Swabian Jura. These lands are rolling and predominantly under cultivation. The Neckar and its tributaries are sunken below the level of these uplands and their slopes have vineyards on tiny holdings with many large villages and small active towns.

The Swabian Jura stretches from the southern end of the Black forest northeast to the Ries lowland. It is a dry limestone plateau with an average width of 40 km. (25 mi.) reaching a height of 600–1,015 m. (1,960–3,330 ft.). To the north it falls abruptly to the Fils valley. The plateau is crossed by several wide deep valleys, with, in places, outlying conical and flat-topped hills on which are situated medieval castles. At the foot of the slopes are orchards and vineyards and above are beechwoods and, at the top, crags of horizontal beds of limestone.

The Danube plateau includes the sheltered and flat stretches of the Danube and then the rolling plateau, dotted with wooded morainic hills, that becomes increasingly hilly toward the shores of Lake Constance.

Population and Administration.—The *Land* had a population of 7,759,154 in 1961 and a density of 562.1 per square mile. It is divided administratively into four districts (North Württemberg, North Baden, South Baden and South Württemberg-Hohenzollern) which comprise 9 urban, 63 rural districts and 3,382 communes.

Baden was established during the Napoleonic wars from a number of scattered counties and dukedoms. It had its beginnings in the margraviate of Baden in the 12th century. The grand duchy, with its approximate present boundaries, lasted until 1918, when the republic was established. Württemberg, one of the oldest states of Germany, had its nucleus in the Neckar valley and capital in Stuttgart, which is now the capital for Baden-Württemberg. The state is about half Catholic and half Protestant. The southern portion is mainly Catholic and looks to Ulm and Freiburg. There are three universities (at Heidelberg, Freiburg im Breisgau and Tübingen) and two technical high schools (Stuttgart, Karlsruhe). The University of Tübingen was renowned for its Protestant scholars and pastors. Stuttgart is the head of the Protestant church of the state, and during the 19th century it was one of the great liberal centres of the *Reich*. Both Baden and Württemberg have always been seats of liberalism.

The Economy.—The economy of Baden-Württemberg gives it a very distinct character. It is a land of predominantly tiny holdings with a large surplus of peasant labour, and of highly skilled industries that have developed through local enterprise with a very slender resource and power base. Yet it retains its traditional folk character in dialect, customs and craftsmanship.

The occupational structure of the *Land* is such that only about one-quarter of the population is dependent on agriculture and forestry. The majority of the inhabitants depend on industry and commerce in North Baden, across the southern half of North Württemberg (centred on Stuttgart, with extensions east to Heidenheim and Ulm, *qq.v.*) and south to Tuttlingen in South Württemberg. Elsewhere almost all the communes have more than two-thirds of their residents dependent on agriculture. The majority of the holdings are under 5 ha. (*c.* 12½ ac.) in extent and they are minutely subdivided with scattered strips. This arises from the practice in the Neckar and in Baden of dividing property equally among the descendants on the death of the owner. In Baden a diversity of crops is grown on the foothill zone (wheat, fruits, chicory, tobacco, vines), but arable farming predominates on the limestones in the northern section. In the Black forest dairying and cattle raising are practised and the high pasture is

used for cattle grazing from May to October. Cheese is one of the chief products. The peasant supplements his slender farm income from the tourist trade and handicrafts (clock making, wood carving, etc). In Württemberg, the Neckar valley is sheltered and has a precipitation of about 600 to 800 mm. (*c.* 23 to 31 in.) and a maximum temperature of 17° C. (62.6° F.) in July and a minimum of −1.8° (29° F.) in January. While wheat and barley predominate on the *Gaue,* vines and fruits are found in the Neckar valley and its tributaries as well as in the better-exposed slopes of the valleys.

Equal subdivision of holdings has long prevailed in this area and accounts for the tiny properties that are inadequate to support the peasants in work or income. Large numbers find occupations in industry in nearby towns as well as in Stuttgart, which has increased at an alarming rate. The law of primogeniture with compact and larger holdings prevails in most of the Black forest and the Danube plateau. The government has long made efforts to consolidate the holdings but there is still one-half of the farm land that is in need of such reform. Large numbers of workers travel to work outside their own villages. With the consolidation of holdings and increased mechanization of agriculture, there is a continuous shift to industry. In a belt from Karlsruhe (*q.v.*) through Stuttgart to Ulm, and around Mannheim (*q.v.*), more than 30% of all the workers (well over a half of the nonagricultural workers) travel to work daily outside the communes in which they live.

Most of the industries of Baden-Württemberg have had long histories based on local enterprise. Engineering and textile industries are the chief of these. There is no coal or lignite but some salt at Heilbronn, Rottweil and Hall. Power needs are met by imports of coal from the Ruhr and the Saar, but most of the power is derived from hydroelectric plants on the Rhine (Lörrach, *q.v.*, and Rheinfelden) and from the Bavarian Alps. Textile, leather, pottery, glass and woodworking industries are found in its many towns. Stuttgart is the industrial and financial heart of Württemberg. Mannheim is the main seat of industry in Baden as well as being a great river port for the import of goods upstream on the Rhine and their distribution throughout the southwest.

For history *see* BADEN; WÜRTTEMBERG.

BAD GANDERSHEIM (GANDERSHEIM) a town of Germany, formerly in the dukedom of Brunswick and after partition of the nation following World War II, in the *Land* of Lower Saxony, Federal Republic of Germany, is situated in the deep valley of the Gande, 48 mi. S.W. of Brunswick. Pop. (1961) 6,115.

It became known for the 11th-century convent church (*Stiftskirche*), containing the tombs of famous abbesses, and the former abbey which was founded by Duke Liudolf of Saxony, who moved to Gandersheim in 852 the nuns who shortly before had been established at Brunshausen. His own daughter Hathumoda was the first abbess, and she was succeeded on her death by her sister Gerberga. Under Gerberga's government, Louis III granted a privilege by which the office of abbess was to continue in the ducal family of Saxony as long as any member of the family was found willing and competent to accept the same. Otto III gave the abbey a market, a right of toll and a mint. After the bishop of Hildesheim and the archbishop of Mainz had long contested with each other about its supervision, Pope Innocent III declared it altogether independent of both. The abbey was ultimately recognized as a holding of the Holy Roman empire, and the abbess had a vote in the imperial diet. The conventual estates were of great extent, and among the feudatories who could be summoned to the court of the abbess were the elector of Hanover and the king of Prussia. Protestantism was introduced in 1568 and Magdalena, the last Roman Catholic abbess, died in 1589; but Protestant abbesses were appointed to the foundation, and continued to enjoy their imperial privileges until 1803, when Gandersheim was incorporated with Brunswick. The last abbess, Augusta Dorothea of Brunswick, was a princess of the ducal house, and kept her rank until her death.

The memory of Gandersheim will long be preserved by its literary memorials. Hrosvitha (*q.v.*), the German dramatist and chronicler, was a member of the sisterhood in the 10th century; and the rhyming chronicle of Eberhard of Gandersheim is probably the earliest historical work composed in Low German. The chronicle, which contains an account of the first period of the monastery, was edited by L. Wieland in the *Monumenta Germ. historica* (1877), and was the object of a special study by Paul Hasse (1872).

The saline baths are located northeast of the town. Manufactures include toys, cigars, aluminum products, chemicals and glass.

BADGER, a carnivorous mammal related to the weasels (family Mustelidae).

The species *Taxidea taxus* occurs in western North America from northern Alberta to central Mexico, principally in open, fairly dry places. It is about 28 in. long, muscular, short-necked and flat-bodied and has a broad, flattened head and short legs and tail. The fur is long, grayish to reddish above and whitish below; the nose, top of head, the feet and spots before and behind the short ears are black. It is a solitary creature that feeds mainly on rodents, but it will eat almost any available animal food. It breeds in late summer but implantation is delayed until mid-winter. Usually two blind young are born in an underground chamber. The badger digs rapidly, easily outdistancing a man with a shovel. It can be a savage fighter; when cornered it turns on its back and rips at an attacker with tooth and claws. Except in extreme cold it does not hibernate but may remain underground for long periods. Badger fur is used commercially, the long, white-tipped hairs being glued into plain black pelts to give a frosted effect. Formerly the best shaving brushes were made with badger hair.

BY COURTESY OF U.S. FISH AND WILDLIFE SERVICE

AMERICAN BADGER (TAXIDEA TAXUS)

The species *Meles meles* occurs widely over Europe and northern Asia. The body is of a dark gray; the head is whitish with a blackish stripe on either side extending through the eye and ear. Although sometimes a pest, it, like the American species, is mainly beneficial because of its predation on rodents.

See CARNIVORE: *Mustelidae.* (K. R. KN.)

BAD GODESBERG (GODESBERG) is a garden city with a 5½ mi. promenade on the Rhine, Germany, which after partition of the nation following World War II was in the *Land* of North Rhine-Westphalia, Federal Republic of Germany. It is situated 4 mi. S. of Bonn on the Cologne-Frankfurt railway line. Pop. (1961) 65,119.

It is a modern spa town (developed in the late 19th century, chartered in 1935) and a popular resort for conferences. Across the Rhine is the Siebengebirge ("seven hills"), a scenic natural park. The federal government holds diplomatic receptions in La Redoute (a rococo mansion and former pump room, completed 1791), and the town is the headquarters of a number of ministries and foreign legations. It was the scene (Sept. 1938) of the preliminary conference between Neville Chamberlain and Adolf Hitler, prior to the Munich pact.

Buildings of historic interest include: St. Martin's church (*c.* 889); the ruined castle, founded by Archbishop Dietrich of Cologne in 1210 and destroyed in 1583 by Duke Ferdinand of Bavaria; and the Muffendorf foundation (1254), former headquarters of the Order of German Knights. Modern buildings include a municipal theatre (1952) and assembly hall with conference rooms (1955).

The industry, principally the manufacture of pharmaceutical products, is smokeless.

BAD HOMBURG (HOMBURG VOR DER HÖHE), a spa of Germany and after partition of the nation following World War II a headquarter town of a *Kreis* (county) in the *Land* of Hesse, the Federal Republic of Germany, lies at the foot of the Taunus mountains, 10 mi. (16 km.) N. of Frankfurt am Main by road.

Pop. (1959 est.) 36,085. The old town is dominated by the castle (1680) whose watchtower dates from the 12th century. Rediscovery in 1834 of the Elisabeth mineral spring led to the foundation of the casino (1841) and the building of the new town centred on the Luisenstrasse (1865). Homburg became an internationally fashionable spa and Edward, prince of Wales (later King Edward VII of England), in the 1890s popularized the Homburg hat of soft felt with dented crown. After 1918 Homburg expanded into a residential town with industries (textiles, leather goods, biscuits, machinery). Nearby is the Saalburg, a reconstructed Roman frontier fortress. (F. SA.)

BAD LANDS, a term originally applied in the middle 1800s to part of southwestern South Dakota, U.S., which the early French-Canadian trappers called *Les Mauvaises terres á traverser* ("the bad lands to cross"). More recently the term badlands has been applied to other areas exhibiting similarly eroded topography, as in North Dakota and other Great Plains states, and some foreign countries.

The South Dakota Bad Lands, also known as the White River Bad Lands and the Big Bad Lands, comprise an area of approximately 2,000 sq.mi. that stretches east and west for 100 mi. along the Jackson-Washabaugh and Pennington-Shannon county lines. The Bad Lands occur mainly on the south side of the White river in the eastern part of this area, but to the west they cross the upland to the Cheyenne river. The Badlands national monument, established in 1939, embraces most of the rugged terrain in Jackson and Pennington counties.

Typical badlands such as those in South Dakota are areas that have been cut into multitudes of deep, tortuous gullies with intervening saw-tooth divides, which extend from the main rivers back to the tablelands, 500 ft. higher. The gully bottoms increase in gradient from almost flat near the main rivers, to nearly vertical at the edges of the tablelands. Because the rocks are not uniform in character, differences in erosion result in stair-step profiles. The joining and separating of the gullies has caused many isolated irregular spires or small flat-topped buttes.

A view from the valleys of the main rivers presents an awesome spectacle of jagged, fluted, seemingly inaccessible hills against the skyline. In contrast, badlands may be approached from the tablelands above with little hint of their presence until the edge of the table is reached, whereupon there is a view of forbidding country just as withering as when seen from below.

Life.—Because of the low rainfall and severe topographic situation, little vegetation can grow except in the flat low areas and on the tablelands. Therefore animal life is also rather meagre. Nevertheless, songbirds, predatory birds, jack rabbits, coyotes and prairie dogs are present in the South Dakota Bad Lands, and within historic time larger grazing animals such as the bison, antelope and mountain sheep were not uncommon.

Geological Formation.—Badlands, although they develop in a semiarid to arid environment, are the result of erosion by water, not wind. The bedrock is poorly cemented, and the rainfall, which comes as summer showers generally of the cloudburst type, can therefore do its erosive work most efficiently. The water that percolates into the pores of the rock likewise does its share of both physical and chemical erosion. Because of the fine grain of the sediments, the dried granular surface material is swept clean from the slopes during showers, along with any small plants that may have gained a roothold since the last shower. Thus the slopes and gullies are nearly always bare.

The rocks of the Bad Lands of South Dakota are only a small remnant of the huge blanket of gravels, sands and clays that was once spread by streams eastward from the rising Rocky mountains, 25,000,000 to 50,000,000 years ago. The climate during much of this time was more humid than now, and the streams were thus able to carry the great quantities of material from the mountains eastward onto the plains.

The three main factors in the development of badlands are: (1) climate with low rainfall that is concentrated mainly in heavy showers; (2) scarcity of deep-rooted vegetation; and (3) poorly cemented, uniform, fine-grained sediments that are horizontally bedded. Any hard layer tends to resist erosion and thus irregularities are caused; the soft clays under the hard layers are cut away, thereby leaving a precipice. Concretionary masses caused by stronger cementation tend to weather into columns. Other irregularities result in the many box canyons and gullies, pinnacles and ridges. Bentonitic (expanding clay) beds tend to weather to rounded, humpbacked surfaces.

Fossils.—The sediments of the badlands areas are known as good fossil-hunting ground not so much because they contain more fossils per unit area, but rather because they are so well exposed to the collector by the badlands type of erosion. The South Dakota Bad Lands became famous for excellent collecting of vertebrate fossils in the early 1850s, and have yielded the remains of land animals that include reptiles (turtle, crocodile), birds and mammals (pig, deer, horse, rhinoceros, sheep, hippopotamus, camel, elephant, cat, dog and the extinct titanothere and oreodont).

BADMINTON, a village in the Cotswold hills, Gloucestershire, Eng., 26 mi. S. of Gloucester and 17 mi. E.N.E. of Bristol by road. Pop. (1951) 367. Badminton house, the seat of the dukes of Beaufort, stands in a park about 10 mi. in circumference. The manor of Badminton was acquired in 1608 from Nicholas Boteler (to whose family it had belonged for several centuries) by Thomas, Viscount Somerset of Cashel (d. 1650 or 1651), third son of Edward, 4th earl of Worcester. It was given by Thomas' daughter and heiress Elizabeth to her cousin's son Henry Somerset, 3rd marquess of Worcester and 1st duke of Beaufort (1629–1700), who built the present mansion (1682) in Palladian style on the site of the old manor house. The game of badminton, a London club, a species of claret-cup, a magazine and a sporting library derived their names from the village.

BADMINTON, a court or lawn game played with lightweight rackets and shuttlecocks. The name was adopted by a group of English army officers home on leave from India in 1873, who played the game at Badminton, the country estate of the Duke of Beaufort, in Gloucestershire, Eng. As a game, history accepts its inception in India by the English military in the early 1870s. They called it Poona. It may have derived from battledore and shuttlecock (*q.v.*). The Badminton association of England, formed in 1893, was the first national organization and the first All England championships for men were held in 1899.

The International Badminton federation (I.B.F.), the world governing body, was formed in 1934. In the second half of the 20th century its membership included 37 member nations and 5 associates. The Thomas cup was presented by Sir George Thomas in 1940 for men's international team competition to be managed by the I.B.F. The first contest was held in Nov. 1948 and the first champion nation was Malaya, winning in 1949. The Uber cup was presented by Mrs. H. S. Uber in 1957 to be competed for by international women's teams in much the same manner as the men's teams. The first competition was in March 1957 and the first champion nation was the United States. Matches are held every three years.

Equipment and Courts.—The badminton shuttlecock (called shuttle or bird) has 14 to 16 feathers with a 2⅛-in. to 2½-in. spread at the top, and weighs from 73 to 85 gr. The temperature and barometric pressure determine the proper weight to be used. Each grain adds four inches to the length of flight. Plastic shuttles are acceptable for general play. The racket (which is of no specified size) usually is strung with 20 gauge gut or high-test nylon and weighs around 5 oz. when strung. Net posts are set just outside the side lines. The net is 30 in. deep and the top line of the net should be 5 ft. 1 in. high at the posts, and 5 ft. in the middle.

The game, sometimes referred to as shuttlecock, consists entirely of volleying, meaning the shuttle must be struck in mid-air before it touches the floor or ground.

The measurements of the court are shown on the accompanying

plan.

The game is played indoors or out and in daylight or artificial light, with two players on each side (called doubles, or if one player is a woman and the other a man, mixed doubles), or with one player on each side (called singles).

It is common practice to mark out a court for both singles and doubles. The length is 44 ft. For doubles it is 20 ft. wide, for singles 17 ft. wide. The lines should be 1½ in. wide. For singles the outside side lines and the long service lines are ignored. For doubles the inside side lines are ignored. There is no legal height for indoor courts other than what a local organization may set. A recommended height is 24 ft. or more. The game often is played informally for exercise on lawns, driveways and beaches, with various adaptations of the rules.

The Game.—The official game is for 15 points except in women's singles when it is for 11 points. A match is the best two out of three games. At the start of a match a player spins a racket and an opponent calls the toss, like heads or tails on a coin. The winner has the choice of serving first or not serving first, or the choice of court ends. The loser has the remaining choice. After each game the opponents change ends, and the winner serves first. If a third game is played, ends are again changed when one side has won 8 points. In an 11-point game ends are changed at 6. A 21-point game may be played, but is not used in sanctioned tournaments. In this game ends are changed at 11 points. When ends are changed in doubles for a new game, either partner may serve or receive first.

There are four basic strokes: (1) the clear, a high shot to the base line; (2) the smash, a very fast, hard hit, downward-angled shot; (3) the drop-shot, a shot that falls rapidly upon crossing the net; and (4) the drive, a fast flat shot hit horizontally near net height. Deception is employed to produce a variation of any one of these basic shots, so that the opponent cannot anticipate what is coming. The velocity of the shuttle in flight reaches 110 m.p.h. but slows down rapidly. The qualified player uses that change of pace in all its varieties. It is a game of speed of action and judgment and great accuracy in placement and control.

For the singles or doubles serve the shuttle must land within the bounds of the proper service court that is being served to. Note that the front service line is the same but the long service and side lines are not. A shuttle hitting any part of a line is deemed to be good; this holds true throughout the game just as in service. The accepted basic serves are, high to the base line in singles and low to the front service line in doubles.

Serving.—The side that is serving is called the IN side, and the receiving side the OUT side. The server and receiver must be in their proper courts. The other two players in doubles may stand anywhere, provided they do not unsight or otherwise obstruct an opponent. In singles the server starts from the right service court and serves to the receiver in the opposite right service court. If the server wins the rally, he scores a point. The next serve is from the left service court to the receiver in the opposite left service court. This process of alternating courts continues as long as the server wins points. Players win points only when on the IN side, meaning serving. When a server loses a rally, he loses the serve (but not a point) and his opponent serves and alternates courts in the same manner. When a player wins the right to serve and his score is an even number, 0–2–4, etc., he starts serving from the right service court; if uneven, 1–3–5, etc., he starts serving from the left service court. In doubles, service always starts with the player properly in the right service court. He serves and alternates courts as long as his side wins. When his side loses the rally, the partner starts to serve. (The side starting the game has only one hand, or serve, in its first inning.) If the score for his side is even, the partners should be in the same service courts they were in when they started the game. The partner now serving serves from whichever service court he belongs in. The OUT side players remain in the service court they belong in when the IN side started to serve. The OUT side players do not alternate service courts. The player served to may alone receive the service.

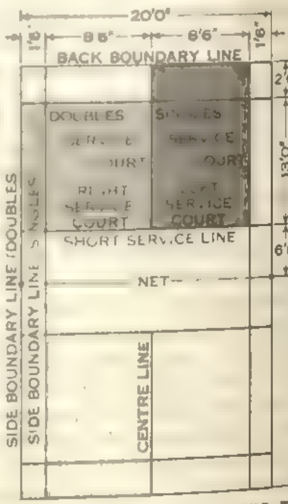
A foot touching a line by server or receiver is a fault. Preliminary feints or otherwise intentional balks are not allowed. The server or receiver may not move his feet until the shuttle has been struck by the server's racket. With the shuttle in play all players may move about the court at will, playing the shuttle back and forth across the net until the shuttle hits the floor, or a player's person or clothing, or fails to cross the net or is uncleanly hit by a player's racket. Either player on a side may hit the shuttle at any time after service, but if both players hit it, or a player hits it twice before it crosses the net, it is a fault (see *Faults*, below).

Setting.—When the score is deuced, that is, tied at 13 all or 14 all, setting is permitted except in women's singles when deuce is 9 or 10 all. When deuce is 13 all, the side reaching 13 first has the choice of setting or not setting. If (singles or doubles) they choose to set, the game then proceeds and the side who wins 5 points first is the winner. If deuce is 14 all and set is chosen, 3 points are played for. If deuce is 13 and set is not chosen, the game has not been altered and goes on to 15 points. However, if the score is then deuced at 14 the rule previously stated applies. If deuced at 9, set is 3 points, and at 10 set is 2 points. In a 21 point game, deuce at 19 is set at 5 and at 20 is set at 3.

Faults.—A fault is a playing violation which ends a rally. A fault made by a player of the IN side puts the side out (in doubles it counts as one hand out); if made by a player whose side is OUT, it counts a point for the IN side.

It is a fault:

1. If, in serving, the shuttle at the instant of being struck is higher than the server's waist.
2. If, in serving, the shuttle falls outside the service court lines.
3. If, either in service or play, the shuttle falls outside the boundaries of the court, or passes through or under the net or fails to pass the net, or touches the roof or side walls, or the person or dress of a player.
4. If the shuttle in play is struck before it crosses to the striker's side of the net.
5. If, when the shuttle is in play, a player touches the net or its supports with racket, person or dress.
6. If in play a player strikes the shuttle (unless he thereby makes a good return) or is struck by it, whether he is standing within or outside the boundaries of the court.
7. If a player obstructs an opponent or invades an opponent's court.



BADMINTON COURT, SHOWING THE MEASUREMENTS FOR SINGLES AND DOUBLES

A let means the play in question is invalidated, therefore played over without penalties. If in service the shuttle touches the net it is not a let provided the service is good otherwise. (If in the course of a rally the shuttle touches and passes over the net, it does not invalidate the stroke.) A let may be given for any unforeseen or accidental hindrance.

In tournaments play is continuous from the first service until the match is concluded, except that (1) in countries where climatic conditions render it desirable, there shall be allowed, subject to the previously published approval of the national governing organization concerned, an interval not exceeding five minutes between the second and third games of a match; and (2) when necessitated by circumstances not within the control of the players. Under no circumstances is play suspended to enable a player to recover his strength or wind, or to receive instruction or advice.

BADOGLIO, PIETRO (1871–1956), Italian soldier who was commander in chief in the Italian conquest of Ethiopia and who led Italy from the German to the Allied side in World War II, was born at Grazzano Monferrato, Piedmont, on Sept. 28, 1871. He entered the army as an artillery officer and saw action in the Italo-Ethiopian War of 1896–97 and in the Italo-Turkish War. During World War I, when he rose to the rank of general, he

planned and carried out the successful attack on Monte Sabotino which preceded the fall of Gorizia in Aug. 1916. He also conducted the armistice preliminaries at Villa Giusti and signed the armistice on behalf of Italy. Having been chief of the general staff from 1919 to 1921, he went as ambassador to Brazil from 1924 to 1925. Made field marshal in June 1925, he again became chief of the general staff. From 1928 to 1933 he was governor general of Libya. In Nov. 1935 he was appointed commander in chief of the Italian forces in Ethiopia, where he was subsequently viceroy for a short time in 1936. Relieved of that office at his own request he was created duke of Addis Ababa. During World War II he was chief of staff from June to Dec. 1940, when he resigned in protest against the Italian invasion of Greece. On the fall of Mussolini (July 25, 1943), which he had been mainly instrumental in organizing, Badoglio was made prime minister. On Sept. 8, 1943, Italy's unconditional surrender to the Allies was announced. Badoglio dissolved the Fascist party, and on Oct. 13 Italy declared war on Germany. He resigned as prime minister in June 1944. Badoglio died at Grazzano Monferrato on Oct. 31, 1956.

See A. Tosti, *Pietro Badoglio* (1956).

BADRINATH, a village and celebrated pilgrimage place in Garhwal district, Uttar Pradesh, India, is 95 mi. N.E. of Hardwar. It lies on the Sarasvati or Vishnuganga river in rugged mountain country near Kamet (25,447 ft.), 17 mi. E. of the Badrinath peak (23,420 ft.). The temple, on a shoulder of the latter at 10,294 ft., contains a shrine of Badarinatha, a title of Vishnu. The place has been famous for over 2,000 years and is mentioned in the *Mahabharata* and several *Puranas.* The long and toilsome route to Badrinath enhances the merits of the pilgrimage.

See F. S. Smythe, *Kamet Conquered* (1932). (F. R. A.)

BADUI, a pagan tribe of about 2,000 persons living in semi-isolation in the mountainous area of Bantam residency in West Java province, Indon. There is little trustworthy information concerning them, but it is said that their religion stresses ancestor worship combined with many prohibitions against the use of ornaments and of foreign (*i.e.,* non-Badui) articles. (F.-C. Ce.)

BADULLA, a town of Ceylon, capital of Badulla district and of Uva province, lies 54 mi. S.E. of Kandy and 2,222 ft. above sea level, almost encircled by a river, the Badulu Oya, and surrounded by mountains, the Namunakuli range to the southwest rising to 6,679 ft. Pop. (1953) 17,043. The town is adorned with flowering trees and is the terminus of the main railway from Colombo. In Kandyan times it was at some periods the seat of a prince but no trace of the palace remains. There are two large Buddhist temples on ancient sites, and a Christian church.

Badulla is the centre of a highly distinctive hilly region of Sinhalese villages set among terraced paddy fields, of tea estates, and of open *patanas* ("grasslands"). The average rainfall is 78 in., with a marked dry season in June, July and August, and the average temperature 73° F. The district extends eastward into Bintenne, a sparsely populated part of the Ceylon dry zone, development of which was begun in the mid-20th century by means of irrigation and other works. (B. H. F.)

BAECK, LEO (1873–1956), leading rabbi, whose refusal to flee from danger during the Nazi regime climaxed his years of services to German Jewry, was born in Lissa, Posen (now Leszno, Pol.), on May 23, 1873, the son of the rabbi and historian Samuel Baeck. He was rabbi in Oppeln, Düsseldorf and Berlin (1912–43), where he also lectured at the Hochschule für die Wissenschaft des Judentums. He served as an army chaplain during World War I. His leadership in German Jewry is indicated by the fact that he was at various times president of B'nai B'rith, the Union of German Rabbis and the Reichsvertretung der Juden. In 1943 Baeck was imprisoned in the Theresienstadt concentration camp, where he lectured on philosophy. By his moral authority he prevented lynching of the guards at liberation in 1945, when he was one of the few survivors.

Baeck's *Essence of Judaism* (1905; English translation 1936, 1948) sees in ethics Judaism's permanent element, recognizes change in forms and stresses the religious paradox (*e.g.,* universalism-particularism), as, in his own life, he mediated between extremes. *Romantische Religion* (1922; English translation included in *Judaism and Christianity,* 1958) described Judaism as the "classical" religion, in contrast with "romantic" Christianity. *Dieses Volk* (1955–57), partly written in Theresienstadt, evaluates the Jews' role in history and deals with the problem of Jewish *Existenz.* A student of Midrash (*q.v.*) and New Testament backgrounds, his collected scientific essays appeared in *Aus drei Jahrtausenden* (1938; 2nd ed., 1958).

After liberation, Baeck lectured in London and at the Hebrew Union college in Cincinnati, O. He died in London on Nov. 2, 1956.

Bibliography.—Theodore Wiener, *The Writings of Leo Baeck,* in *Studies in Bibliography and Booklore,* vol. i, pp. 108–144 (1954). *See* also *American Jewish Year Book 1958,* pp. 478–482; the *Synagogue Review,* pp. 137–141 (Jan. 1957); Leo Baeck Institute of Jews from Germany, *Year Book, 1956–1957,* ed. by Robert Weltsch, 2 vol. (1956–58). (J. J. Pi.)

BAEDEKER, the name of a German publishing house, issuers of a famous series of guidebooks. The founder of the firm, Karl Baedeker (1801–59), was born at Essen, Nov. 3, 1801, son of a printer and bookseller. In 1827 he started a firm at Koblenz and two years later brought out a guidebook to the town. It was in the second edition of a guide to the Rhine from Mainz to Cologne (which had appeared in 1828) that Baedeker evolved the system on which he based his series. His aim was to give the traveler the practical information necessary to enable him to dispense with paid guides. He checked the reliability of his publications by incognito journeys and consulted the best sources and experts. A notable feature of his guides was the use of "stars" to indicate objects and views of special interest, as well as reliable hotels. At his death (Koblenz, Oct. 4, 1859) much of Europe had been covered by his guidebooks. Under the ownership of his sons, Ernst (d. 1861), Karl (part-owner until 1878) and especially Fritz (1844–1925), the firm expanded still more. The first French edition appeared in 1846, the first English one in 1861. The house moved to Leipzig in 1872, in 1948 to Hamburg and in 1956 to Freiburg in Breisgau. A branch devoted to motor guides was opened in Stuttgart in 1952. (M. Kl.)

BAEKELAND, LEO HENDRIK (1863–1944), Belgian-born industrial chemist particularly well known for his discovery of Bakelite, was born in Ghent, Nov. 14, 1863. He taught at the University of Ghent after receiving his doctorate there with highest honours at the age of 21. In 1889 he went to the U.S. and joined a photographic firm; later, as a consulting chemist, he developed a photographic paper, which he called Velox, that could be developed in artificial light. When he sold his rights to George Eastman in 1899 he became independently wealthy. In 1905 he began research into methods of creating synthetic resins; the result was his discovery of Bakelite, a condensation product of formaldehyde and carbolic acid produced at high temperatures and pressures; it was one of the first modern plastics.

Baekeland died in Beacon, N.Y., Feb. 23, 1944; his patient and carefully planned researches had been richly rewarded with honours, wealth and the satisfaction of great and genuine accomplishment. (W. E. Hd.)

BAEL FRUIT, the fruit of the bael or bel fruit tree (*Aegle marmelos*), also known as Bengal quince, which is found wild or cultivated throughout India. *Aegle* is a genus of the rue or citrus family (Rutaceae) containing three species, two in tropical Asia and one in west tropical Africa. The trees bear strong spines; alternate, compound leaves, each with three leaflets; and panicles of sweet-scented white flowers. The tree is valued for its fruit, which is oblong to pyriform in shape, two inches to five inches in diameter and has a gray or yellow rind and a sweet, thick orange-coloured pulp. The unripe fruit is cut in slices, sun-dried and used as a remedy for dysentery; the ripe fruit is described as sweet, aromatic and cooling. The wood is yellowish-white and hard but not durable.

BAER, KARL ERNST VON (1792–1876), German pioneer in comparative embryology who discovered the mammalian ovum and the notochord, was born at Piep, Estonia, on Feb. 29, 1792. In his 18th year he entered Dorpat university as a medical student, but, attracted by the study of life history, he moved to

Germany, where J. I. J. Döllinger (1770–1841), father of the Catholic theologian, was professor of anatomy at the University of Würzburg. Döllinger gave a direction to Baer's studies that secured his future pre-eminence in the science of organic development. Baer collaborated with C. H. Pander (1794–1865) in researches on the development of the chick, the results of which were first published in K. F. Burdach's treatise on physiology. Continuing his investigations alone, Baer extended them to the development of organisms generally; and after a sojourn at Berlin he was invited by his old teacher Burdach, who had become professor of anatomy at Königsberg, to join him as prosector and chief of the new zoological museum (1817). Baer's discovery of the human ovum was the subject of his *Epistola de Ovo Mammalium et Homini Genesi* (1827), and in 1828 he published the first part of his *History of the Development of Animals* (*Über die Entwickelungsgeschichte der Thiere*), the second part following in 1837. In this work he demonstrated that the Graafian follicles in the ovary are not the actual eggs, but that they contain the true ovum. He next showed that in all vertebrates the primary stage of cleavage of the fertilized egg is followed by modification into leaflike germ layers (skin, muscular, vascular and mucous) from which arise the different organs of the body by differentiation. He advanced the "law of corresponding stages" concerning the development of vertebrate embryos. By deliberately leaving off the labels of specimens, he subtly demonstrated the similarity of stages in different classes. "I am quite unable to say to what class they belong. They may be lizards, or small birds, or very young mammalia, so complete is the similarity in the mode of formation of the head and trunk in these animals. The extremities are still absent, but even if they existed, in the earliest stage of the development we should learn nothing, because all arise from the same fundamental form." Baer further discovered the gelatinous, cylindrical cord, known as the notochord, which passes along the body of the embryo of vertebrates, in the lower types of which it is limited to the entire inner skeleton, while in the higher the backbone and skull are developed round it. In his *History of Development* he suggests, "Are not all animals in the beginning of their development essentially alike, and is there not a primary form common to all?" (i, p. 223). Notwithstanding this, the "telic" idea, with the archetypal theory that it involved, possessed Baer to the end of his life, and explains his inability to accept the theory of unbroken descent with modification.

The influence of Baer's discoveries was far reaching and abiding. Not only was he the pioneer of comparative embryology, but the impetus to T. H. Huxley's researches on the structure of the jellyfish came from him (*Life*, i, 163), and Herbert Spencer found in Baer's "law of development" the "law of all development" (*Essays*, i, 30).

In 1834 Baer was appointed librarian of the Academy of Sciences of St. Petersburg. In 1835 he published his *Development of Fishes*, and as the result of collection of all available information concerning the fauna and flora of the polar regions of the empire, he was appointed leader of an arctic expedition in 1837. The remainder of his active life was occupied in diverse fields of research, geological as well as biological, an outcome of the latter being his fine monograph on the fishes of the Baltic and Caspian seas. One of his last works was an interesting autobiography published at the expense of the Estonian nobles on the celebration of the jubilee of his doctorate in 1864. Baer died at Dorpat, Estonia, on Nov. 28, 1876. (J. Rm.)

BAER, WILLIAM JACOB (1860–1941), U.S. painter, who had much to do with the revival in America of the art of miniature painting, was born on Jan. 29, 1860, in Cincinnati, O. He studied at Munich in 1880–84. He turned to miniature painting in 1892, and was the first president of the Society of Painters in Miniature. Among his miniatures are "The Golden Hour," "Daphne," "In Arcadia" and "Madonna With the Auburn Hair." He died Sept. 21, 1941.

BAETYLUS (Baetulus), a Greek word of Semitic origin (= *bethel*) denoting a sacred stone or pillar. Numerous holy or fetish stones existed in antiquity, generally attached to the cult of some particular god and looked upon as his abiding place or symbol. They were, at any rate originally, meteorites worshiped as divine manifestations. The most famous example is the holy stone at Delphi, the omphalos ("navel"), which reposed in the temple of Apollo and marked the exact centre of the universe. A second stone at Delphi, near the sanctuary of Neoptolemus, was said to have been the one that Cronus (*q.v.*) swallowed; it was thought to be Zeus himself in his symbolic or baetylic form. Another famous stone was that of Cybele, at Pessinus (see Great Mother of the Gods).

ALINARI
MARBLE REPRESENTATION OF THE OMPHALOS AT DELPHI

In some instances, an attempt was made to give a more regular form to the original shapeless stones by forming them into pillars or into groups of three pillars. Such columns were sometimes placed before a shrine where the worshiper adored; others were used as mileposts and often shaped into human form. According to Ernest Gardner, baetyli in Aegean religion were probably representations in cult form of the divine mountain. In turn, the baetylus was the parent form for altars and iconic statuary. *See* also Herm. (T. V. B.)

BAEYER, (JOHANN FRIEDRICH WILHELM) ADOLF VON (1835–1917), German chemist, is best known for his investigations in organic chemistry and, in particular, synthetical studies by the aid of "condensation" reactions. He was born in Berlin on Oct. 31, 1835. His father was Johann Jacob von Baeyer (1794–1885), chief of the Berlin Geodetical institute from 1870. Baeyer studied chemistry under R. W. Bunsen and especially F. A. Kekulé, and in 1858 took his Ph.D. degree at Berlin, becoming *Privatdocent* in 1860. He headed the chemistry laboratory at the Berlin Gewerbeinstitut until 1872, when he was appointed professor of chemistry at Strasbourg. In 1875 he was called in the same capacity to Munich as successor to Justus von Liebig.

The Royal Society of London awarded Baeyer the Davy medal in 1881 for his researches on indigo, whose nature and composition he did more to elucidate than any other chemist, and which he also succeeded in preparing artificially, though his methods were not found commercially practicable. To celebrate his 70th birthday his scientific papers were collected and published in two volumes (*Gesammelte Werke*, 1905), and the names of the headings under which they are grouped give some idea of the range and extent of his chemical work: (1) organic arsenic compounds; (2) uric acid group; (3) indigo; (4) papers arising from indigo researches; (5) pyrrol and pyridine bases; (6) experiments on the elimination of water and on condensation; (7) the phthaleins; (8) the hydroaromatic compounds; (9) the terpenes; (10) nitroso compounds; (11) furfurol; (12) acetylene compounds and "strain" (*Spannungs*) theory; (13) peroxides; (14) basic properties of oxygen; (15) dibenzal-acetone and triphenylamine; (16) various researches on the aromatic series; and (17) the aliphatic series. He was awarded the Nobel prize for chemistry in 1905 "in recognition of his services in the development of organic chemistry and the chemical industry through his work on organic dyes and hydroaromatic combinations." Baeyer died at Starnberg near Munich on Aug. 20, 1917.

For detailed biographical accounts *see* W. Perkins, "Baeyer Memorial Lecture," *Journal of the Chemical Society* (1923); F. Henrich, *Journal of Chemical Education* (1930); E. Farber, *Nobel Prize Winners in Chemistry, 1901–1950* (1954). His autobiographical *Erinnerungen aus meinem Leben* (1905) covers only the first half of his life.

BÁEZ, BUENAVENTURA (1810–1884), president of the Dominican Republic, was born at Azua de Compostela in 1810. He believed that Dominican freedom from Haiti could be assured only by the establishment of a protectorate under a foreign power.

During the uprising of 1844 he joined Gen. Pedro Santana, whom he won over to his views. The Santana-Báez coalition controlled the country until a rift led to Báez' downfall in 1853. He spent several years in exile, returning after Santana's death to reoccupy the presidency briefly in 1865–66. As president again in 1868 he contracted a ruinous loan in London, and his attempt in 1869 to promote Dominican annexation or the lease of Samaná bay (*q.v.*) to the United States failed when the U.S. senate did not ratify the treaties in question. Overthrown in 1874, he regained the presidency for the fifth and last time in 1876. Another revolt forced his flight in March 1878 to Puerto Rico, where he died in 1884. *See* DOMINICAN REPUBLIC: *History*. (K. M. S.)

BAFFIN, WILLIAM (1584?–1622), English navigator and discoverer who searched for the northwest passage and gave his name to Baffin Island and Baffin bay, was probably born in London about 1584. He made numerous scientific and magnetic observations, one of which (the determination of longitude at sea by lunar observation) is said to have been the first of its kind on record, and he also made important surveys in the Red sea and the Persian gulf. The earliest mention of his name occurs in 1612 in connection with an expedition in search of a northwest passage under the orders of Capt. James Hall, whom he accompanied as chief pilot. During the two following years Baffin served in the Spitsbergen whale-fishery, at that time controlled by the Muscovy company. In 1615 he entered the service of the company and made another attempt to discover a northwest passage. He accompanied Capt. Robert Bylot as pilot of the little ship "Discovery," and they carefully examined Hudson strait. The accuracy of Baffin's tidal and astronomical observations on this voyage was confirmed in a remarkable manner by Sir Edward Parry when passing through the same area two centuries later (1821). In the following year Baffin again sailed as pilot of the "Discovery" and passing up Davis strait discovered the fine bay to the north that now bears his name, together with the magnificent series of straits which radiate from its head and were named by him Lancaster, Smith and Jones sounds, in honour of the patrons of his voyages. On this voyage he had sailed over 300 mi. farther north than his predecessor J. Davis, to about latitude 77° 45′. All hopes, however, seemed now ended of discovering a passage to India by this route, and in course of time even Baffin's discoveries came to be doubted until they were rediscovered by Captain Ross in 1818. In the service of the East India company, Baffin undertook a voyage to British India (1617–19), and on his return received the special recognition of the company for certain valuable surveys of the Red sea and Persian gulf which he had made in the course of the voyage. Early in 1620 he again sailed to the east, and in the Anglo-Persian attack on Qishm in the Persian gulf, preparatory to the reduction of Ormuz, he was killed on Jan. 23, 1622.

See *The Voyages of William Baffin 1612–1622*, ed. by Sir Clements Markham (1905).

BAFFIN ISLAND, an arctic island, lying between Greenland and the Canadian mainland, was named after the 17th-century English explorer William Baffin. Baffin Island (area 183,810 sq.mi.), a part of the district of Franklin, Northwest Territories, is separated from Quebec and Labrador by Hudson strait. It includes a northwestern plateau, east coast mountains (to 7,000 ft.), a southeastern plateau and a western lowland. The mountain region contains many glaciers. Amadjuak and Nettilling are the largest lakes. The population (3,387 in 1961) is largely coastal. There is an international airport beside Frobisher bay at the southern end of the island. Other settlements include Pangnirtung on Cumberland sound and Arctic bay on Admiralty inlet. Coal is mined and there is iron ore on the island.

Baffin Bay.—Separating Baffin Island from Greenland, Baffin bay merges in the south with Davis strait and in the north with Smith sound. Its maximum depth exceeds 1,500 fathoms. A mild ocean current flows up its east side and a cold one down its west side. Floating ice persists all summer in the west.

See also NORTHWEST TERRITORIES. (H. R. TN.)

BAG, one of the oldest forms of packaging (*q.v.*), being a direct outgrowth of handwrapping, the earliest method. The formation of a bag, or sack, from a flexible piece of packaging material was a logical development following the introduction of glue and sewing skills.

Originally, all bags were fabricated by hand from heavy fabrics, such as closely woven flax, jute and hemp. As paper came into general use, it became the most widely used bagmaking material and was fabricated into bags by craftsmen using such basic tools as a knife, a pot of glue and a brush.

Basic Manufacturing Process.—By the early 1960s practically all bags were made by machine. A bag is essentially a tube or rectangular cylinder with a bottom, and the basic equipment required for bag manufacture consists of a machine described as a tuber or "former" and a bottomer.

This machinery works from a continuous web coming from a roll of bagmaking material placed in front of the machine and threaded through rolls to a metal plate called the "former," which is as wide as the bag is to be and forms the material into the shape of a tube. The tube is cut off to the desired length, and the seam of the bag is fabricated on the machine. The next step, bottoming, is done on the bottoming cylinder. After pressure is applied to secure the seam and bottom, the bag is ready for use.

There are many variations of this process, depending upon the materials involved, the size of the bag, the type of seam and bottom (pasted, sewn, taped or heat-sealed) and the use made of the bag. However, the idea of a tube with a bottom is basic to all bag manufacturing.

Materials and Uses.—*Paper.*—Paper is the most widely used bagmaking material. Most paper bags are fabricated from kraft (brown) paper in natural or bleached form and range in variety from the standard grocery bag used for packaging consumer purchases to the large multiwall shipping sack consisting of three to six walls of paper (actually a combination of three to six bags in one). Multiwall bags have a capacity of from 25 to 100 lb. and are used for packaging grain, cement, fertilizers, chemicals, etc. Kraft paper is also fabricated into larger bags and covers for packaging such products as mattresses, furniture and automobiles.

Other types of paper, such as glassine, vegetable parchment and the waxed grades, are also used in bag manufacture for certain food and specialty packaging uses.

Cellophane.—Cellophane is commonly used for manufacturing transparent bags. It is durable, moisture resistant, and impervious to air, grease, odour and dirt. Because of its transparency, cellophane is used for packaging food products, dry goods and other products with eye appeal.

Plastic Film.—This material, including polyethylene, Pliofilm, polypropylene, Mylar and vinyl, has gained wide popularity for bags and sacks. The chemical and physical properties of these plastic films make them useful for a number of different types of bags. The fact that many of the films are chemically inert, light in weight, odourless, tasteless, moisture-proof, nontoxic and flexible at subzero temperatures adapt them for use in packaging produce, poultry, sea food, textiles, hard goods, granular products, frozen foods, etc.

Aluminum Foil.—The use of aluminum foil in bag manufacturing has greatly expanded because of the protection it provides against the spoilage effects of moisture and rancidity. Foods and many nonfood products such as powdered chemicals frequently are packaged in foil bags.

Textiles.—Textile bags are generally fabricated from burlap or cotton fabric. They are commonly made with a conventional sewn seam, although in some cases cemented seams are used. The types of product commonly packaged in textile bags are chemicals, certain types of produce, fertilizers and minerals. (W. V. D.)

BAGA, a Negro people numbering about 45,000 (1960s) who inhabit the swampy coastal region between Cape Verga and Conakry in the Republic of (former French) Guinea. They are said to speak a semi-Bantu tongue related to the Temne and Kissi languages. The women cultivate rice; the men fish and tend palm and kola trees. Political, social and religious authority reside in the Simo society with several grades. Marriage is said to be obligatory between (1) the husband's brothers and his wife's sisters and (2) the younger brother or nephew and the widow. Inherit-

ance passes in the maternal line. The dead are exposed, before burial in a sacred grove, and their houses, with some possessions, are burned. Most villages are Islamized. It is not unlikely that some villages of the *Baga foré* group on the Rio Nuñez and the Rio Pongo have remained animist, but it is doubtful whether the enormous *nimba* masks, formerly used in fertility rites during rice harvest time, are still in use. *See* also Los Islands.

Bibliography.—A. Arcin, *La Guinée Française* (1907); D. Paulme, "Structures sociales en pays Baga," *Bull. Inst. fr. Afr. noire,* vol. 18 (1956); G. P. Murdock, *Africa: Its Peoples and Their Culture History* (1959). (L. So.; W. B. Fg.)

BAGASSE, the residue from the milling of sugar cane, consisting of the fibrous structure of the cane, some unextracted juice, and 40% to 50% water; also called "megass" (a word of unknown origin) in Australia and other areas of the British commonwealth. Formerly, the residue of beet-sugar manufacture was called bagasse, but the term "beet pulp" has replaced this usage.

The word bagasse (Spanish *bagazo*) comes from the French *bagage* and originally meant rubbish, refuse or trash. Applied first to the husks of olives, palm nuts and grapes after pressing, the meaning was extended to include the residues from other processed plant materials, such as sisal and the sugar cane and sugar beet. In modern usage, however, the word is almost invariably limited to mean the end-product of sugar-cane milling.

See Sugar: *Cane Sugar Manufacture: Bagasse.* (G. P. Me.)

BAGATELLE, a game probably of English origin, is very likely a modification of billiards, and is played on an oblong board or table varying in size from 6 ft. by 1½ ft. to 10 ft. by 3 ft. Ordinary billiard cues and nine balls, one black, four red and four white, are used. The black ball is placed upon a spot about 9 in. in front of hole 1, and about 18 in. from the player's end of the board. A line (the balk) is drawn across the board, from behind which the players shoot.

BY COURTESY OF MESSRS. THURSTON AND CO., LTD.

BAGATELLE BOARD

The game is played with billiard cues and nine balls

Bagatelle Proper.—The black ball having been placed on the upper spot, the players "string" for the lead, the winner being that player who plays his ball into the highest hole. Any number may play. Each player in turn plays all eight balls up the table, no score being allowed until a ball has touched the black ball, the object being to play as many balls as possible into the holes, the black ball counting double. The game is decided by the aggregate score made in an agreed number of rounds.

Sans Egal.—This is a French form of the game. Two players take part, one using the red and one the white balls. After "stringing" for lead, the leader plays at the black, forfeiting a ball if he misses. His opponent then plays at the black if it has not been touched, otherwise any way he likes, and each then plays alternately, the object being to hole the black and his own balls. If a player holes one of his opponent's balls it is scored for his opponent.

The Cannon Game.—As in billiards, three balls are required. The object of the game is to make cannons (caroms), balls played into holes at the same time counting the number of the holes, but if a ball falls into a hole during a play in which no cannon is made the score counts for the adversary. A cannon counts two; missing the white object ball scores 1 to the adversary; missing the black, 5 to the adversary.

Mississippi.—This variation is played with a bridge pierced with nine or more arches; according to the size of the table, the arches being numbered from one upward. All nine balls are usually played, though the black is sometimes omitted, each player having a round, the object being to send the balls through the arches. This may not be done directly, but the balls must strike a cushion first. A ball, lying in front of the bridge, may be sent through by the cue ball if the latter has struck a cushion. If a ball falls into a cup the striker scores the value of the cup as well as of the arch.

Bell-Bagatelle.—Although the popularity of bagatelle has waned the principle of this version, played on an inclined board equipped with cups, stalls and arches hung with bells, has survived in many children's games using small inclined boards and marbles or small steel or plastic balls instead of billiard balls and a spring bolt, or plunger, instead of cue sticks. An elaboration is the coin-operated pinball machine, outlawed in many places as a gambling device. (F. Hn.)

BAGÉ (Bajé), a town in southern Rio Grande do Sul state, Brazil. It is 110 mi. by rail N.W. of Pelotas. Pop. (1960) 47,930. It is situated at an elevation of 774 ft. in the midst of gently rolling hills covered with tall prairie grass. The surrounding country is used chiefly for cattle and sheep ranching, and in Bagé there are meat-packing plants where the chief product is *xarque* or jerked beef. It is also a wool depot. Nearby there is an important government experimental farm where specialists on animal husbandry are developing better feeding techniques. Experiments in growing wheat in this area have been only moderately successful. The town can be reached by rail, highway or air. Located approximately 25 mi. from the Uruguayan border, it has long been a place of military importance. In 1827 it was captured by the Argentineans then invading southern Brazil. (P. E. J.)

BAGEHOT, WALTER (1826–1877), English economist, political analyst, sociologist and editor whom Lord Bryce described as "the most original mind of his generation." He was born at Langport, Somersetshire, where his family were general merchants, on Feb. 23, 1826. His mother was the sister of Vincent Stuckey, the head of the largest private bank in the west country. He was educated at Bristol college, then a brilliant centre of nonconformist teaching, and at University college, London, where he graduated with the university's gold medal in philosophy. A close friendship which he formed, while reading for the bar, with Arthur Hugh Clough, made him abandon the career and join his father in Stuckey's bank.

From 1852 to 1858 he lived the life of a country banker, but his association with the *Prospective Review,* edited by his closest friend, Richard Holt Hutton (later editor of *The Spectator*), gave him the opportunity to write during this period some of the finest of his literary essays. In 1858 he married the eldest daughter of Sir James Wilson, financial secretary to the treasury in Lord Palmerston's government, and the owner and founder of *The Economist.* When Sir James died in 1860, Bagehot assumed full control of the paper, making it the most influential economic weekly in Europe. Though he twice failed of election to parliament as a Liberal, his friendship with Gladstone, Cornewall Lewis, Carnarvon, Granville, Goschen and other Liberal and Conservative leaders gave him a position of discreet but considerable influence in London. He was closely consulted on economic questions by Gladstone and in the year of his death devised a new security, the treasury bill, to enable the British government to finance its short-term obligations.

Bagehot was a high-spirited man of great charm and humanity but with frail health and nerves which forced upon him the role of observer rather than combatant in the great controversies of his day, to which are owed the four books on which his reputation has come to rest. Of these, *The English Constitution* (1867) was the first effective attempt to distinguish between the real and formal centres of power in the British constitutional system. *Physics and Politics* (1872), the most original of his works, was an attempt to apply the concept of evolution to the origins and development of societies: it broke ground, particularly in the concept of unconscious imitation as a molding force. *Lombard Street* (1873), intended to explain the necessity for keeping a greater reserve in the hands of the Bank of England, really first formulated the modern theory of central banking. *Economic Studies* (1880) was a fragment of a larger book in which Bagehot had intended to explore the economic structure of the world of the 1870s as Adam Smith had done for his world a century earlier.

Bagehot's enduring gifts to English literature were a fresh and natural style which influenced letters and journalism both in Britain and the United States, and an approach to facts, economic, political or social, that was both imaginative and realistic. He died at Langport on March 24, 1877.

Mrs. Russell Barrington edited *The Works and Life of Walter Bagehot* in ten volumes (1915).

See Norman St. John-Stevas, *Walter Bagehot* (1959); William Irvine, *Walter Bagehot* (1939). (A. F. Bu.)

BAGGARA (properly *Baqqara,* or "cattle-men") are nomad Arabs who have been forced by circumstance to live in a part of Africa which will support the cow but not the camel—south of latitude 13° and north of latitude 10° from Lake Chad eastward to the Nile. Apart from the Seleim and their neighbours on the White Nile, who seem to have followed a more northerly route, the bulk of the present tribes are the descendants of Arabs who migrated west out of Egypt in the middle ages, turned south from Tunisia to Chad, and finally moved back eastward in the 18th and 19th centuries. They numbered about 5,000,000 in the 1960s.

As a result of association with local peoples such as the Fulani (*q.v.*) of Nigeria they have acquired a western appearance, a distinct dialect of Arabic and dark skins. Their characteristic weapon is a long broad-bladed spear and their wide-sleeved *jibba* in its patched form became the uniform of the Mahdi's army. The Khalifa Abdullah was himself a Ta'aishi Baggari and so were most of his emirs. The Baggara claim descent from Abdullah al-Guhani, but their tribal units are in fact the result of association. Gubarat and Salamat, tribes in their own right in the west, appear as subsections of eastern tribes, and Mahria, Nawaiba and Mahamid, camel-owners in Wadai, have Baggara sections among the Rizeigat.

They are a warlike, quarrelsome, fissiparous people, devoted to their cattle and horses, fond of fighting, hunting and dancing, and they cultivate crops, such as cotton, only as a means to the purchase of more cattle. Their women have much more freedom than those of the camel-owners. *See* also SUDAN, REPUBLIC OF THE: *History* and *The People;* BEDOUIN; DARFUR; KORDOFAN.

Murdock, "Baggara," in *Africa: Its Peoples and Their Culture History* (1959); P. M. Holt, "Bakkara," in *The Encyclopaedia of Islam,* vol. 1 (1960). (K. D. D. H.)

BAGGESEN, JENS IMMANUEL (1764–1826), Danish writer, who reflects the tendencies of both classicism and romanticism, was born in Korsor, Den. (Feb. 15, 1764), of poor and religious parents. He was a gifted and extremely sensitive child. In 1782 he went to study in Copenhagen, where his personal charm and his early poems, especially the satirical *Komiske Fortaellinger* ("Comical Tales"; 1785), gained him entry to literary circles and to the homes of the liberal-minded nobility. After the failure of his opera *Holger Danske* he visited Germany, Switzerland and France (1789–90), giving an account of his travels in *Labyrinthen* (1792–93), an imaginative prose work reminiscent of Sterne, exceptional in the felicity of its language and thought. Baggesen was an impressionable, eager spirit in a period unusually rich in ideas. He was influenced by, and inveighed against, both 18th-century rationalism and the new romanticism. He became a disciple of Kant (whose name he adopted) and of Rousseau, was an ardent supporter of the French Revolution, but after 1800 was drawn to romanticism, as is evident in the self-critical poem *Gengangeren og han selv* ("The Ghost and Himself"; 1807). After 1813 however he embarked on a long controversy with the romantics.

Baggesen's life was as unsettled as his spirit; constantly on the move, he lived both in Denmark and abroad (especially in Paris, where he spent his last years), plagued by personal sorrows. He died in Hamburg, Oct. 3, 1826. Typically Danish in his wit and humour, he was a master of the rhymed epistle, though in *Thora fra Havsgaard* (1814–16) he turned to the epic form. Among his works in German, which he wrote with almost equal fluency, are *Parthenaïs, oder die Alpenreise* (1802), *Heideblumen* (1808) and two parodies of German romanticism, *Der Karfunkel- und Klingelalmanach* (1810) and *Der vollendete Faust* (see *Poetische Werke in deutscher Sprache,* i–v (1836).

See *Danske Vaerker,* 12 vol. (1827–32); *Poetiske Skrifter,* 5 vol. (1889–1903). *See* also A. Baggesen, *Jens Baggesens Biographi,* 4 vol. (1843–56); K. F. Plesner, *Baggesen-bibliografi* (1943). (S. M. K.)

BAGHDAD a *liwa* ("province"), one of the seven constituted from the Ottoman vilayet of Baghdad, Iraq. Pop. (1965) 2,124,-323. Area 7,692 sq.mi. It corresponds broadly to the cultivated zone on both sides of the Tigris river together with an irrigated area on the left bank of the Euphrates system, including associated irrigation and drainage channels, and is largely surrounded by a zone of uncultivated desert. The *liwa* has reasonable geographical unity, except that a stretch of desert between Mandali and Kut is included with Baghdad, thus separating the *liwas* of Diyala and Kut. In the west, irrigation comes from five major intakes from the Euphrates, which serve a region extending almost to the Tigris; east of the Tigris the canals come mainly from the Diyala system. Most of the inhabitants live by agriculture. In the *liwa* are the sites of the ancient cities of Ctesiphon, Seleucia, Sippar, Agade and Samarra (*qq.v.*). (W. B. Fr.)

BAGHDAD, the foremost city of Mesopotamia and the capital of modern Iraq and Baghdad *liwa* ("province"), is situated on the Tigris at the point where the river is nearest to the Euphrates (25 mi.). Pop. (1957) 355,958. The city was originally built on the west bank of the river, but for more than 1,000 years the greater part has been on the east bank. There is, however, a large and growing suburb on the west side, comprising the quarters of Al Karkh, Karradet Mariam and Al Mansur, and including the principal railway station and the airport as well as the parliament building. The main city is linked with these quarters by four road bridges, one of which also carries a railway. A fifth bridge leads to Kadhimain (Al Kazimiyah), north of Al Karkh, a considerable settlement which has grown up around the tombs of Musa al-Kadhim and Mohammed al-Jawad, the 7th and 9th of the 12 imams recognized as the true successors of the Prophet by the majority of Shi'ah Muslims. The tombs of the two imams, and the adjacent mosque, are among the most important centres of Shi'ah pilgrimage.

After World War II Iraq's oil revenues considerably increased, and the new wealth of the country is reflected in the capital, whose merchants are now concerned with the import and distribution, and to a lesser but growing extent the manufacture, of capital and consumer goods. Most of Iraqi industries are in Baghdad and include leather, silks, cotton stuffs, cement, tobacco products and arrack distilling (from dates and grapes). There are also railway workshops. Residential garden suburbs have grown up on both banks of the Tigris, and the crowded houses and shops of the old city, which were not for the most part of great antiquity or interest, are being replaced by wide streets and new office blocks, stores and hotels. The completion of the Tigris barrage at Samarra has

BY COURTESY OF THE IRAQ DIRECTORATE GENERAL OF ANTIQUITIES

MOSQUE AT KADHIMAIN (AL KAZIMIYAH), COMPLETED IN THE 19TH CENTURY

relieved Baghdad of the danger of disastrous floods, which caused severe damage on many occasions in its history.

The city is the cultural centre of Iraq and has a university (founded 1958, with a college of engineering at Bab al Mu'adhdham [Al A'zamiyah]), various research institutes, libraries and museums of antiquities.

In the course of the 19th century a number of schemes were put forward to improve the communications of Baghdad. A survey of the Euphrates and the lower Tigris by Col. F. R. Chesney in 1836 demonstrated the impracticability of steam navigation down the Euphrates, but was followed in 1860 by the establishment of a regular steamer service on the Tigris between Baghdad and Basra. Proposals for a Euphrates valley railway also proved impracticable, and Baghdad was not finally linked with Europe by rail until the completion, in 1940, of the line from Istanbul begun by the Germans before 1914 (*See* BAGHDAD RAILWAY). The 20th century saw the creation of new routes for trade and travel. A regular motor service between Baghdad and Damascus was instituted in 1923, and the Cairo-Baghdad airmail service, inaugurated in 1921, was followed by a passenger service in 1929. The airport is now an important staging point for many international airlines linking Europe with the far east and Australia.

History.—Many capital cities have stood in the vicinity of Baghdad, where the ancient trade routes of the Euphrates, Tigris and Diyala valleys converge: Agade, Babylon and Burj Aqarquf, the Kassite capital, lay to the west; Seleucia and Ctesiphon about 20 mi. to the south. In A.D. 750 the caliphate was established in Iraq with the foundation of the Abbasid dynasty by Abu 'l-Abbas, whose brother and successor Abu Ja'far known as Al-Mansur determined in 762 to build himself a new capital on the site of a Sassanian village, Baghdad. The Round City of Mansur, called Madinat al-Salaam, the City of Peace, stood on the west bank of the Tigris, but no traces of its buildings remain and its exact site is unknown. It was 3,000 yd. in diameter, with three concentric walls each pierced by four gates, through which passed highways radiating from the caliphal palace at the centre of the city to the four quarters of the empire. Bazaars were not permitted within the city, and a merchants' quarter, Al Karkh, developed outside the Basra gate. From the northeast gate the Khurasan road crossed the Tigris on a pontoon bridge, and beyond this on the east bank lay the palace of Al-Mansur's heir apparent, Al-Mahdi, around which grew up the three suburbs of Al Rusafah, Al Shammasiyah and Al Mukharrim, the earliest forerunners of the modern city. Baghdad reached the zenith of its prosperity under Harun al-Rashid (*q.v.*), son of Al-Mahdi, who accumulated in his capital the riches and learning of the known world. Many tales reflecting the glory of this period occur in the *Thousand And One Nights* (*q.v.*). Harun's death was followed by civil war between his two sons, during which the Round City was severely damaged. It was never fully restored; from 836 to 892 the caliphs abandoned Baghdad, where their unruly Turkish bodyguard had become unpopular, for a new capital at Samarra, and after their return they resided in Mukharrim on the east bank. In 1095 a new wall was built around east Baghdad, which survived with many restorations until the 19th century, when it was largely dismantled. One of the two surviving gates, the Talisman gate, was blown up by the retreating Turks in 1917; the second, Bab al Wastani or the Middle gate, still stands and was restored as an arms museum. A few other buildings survive from the Abbasid period, notably the so-called Abbasid palace and the Mustansiriyah, a large law college built and endowed by the caliph Mustansir in 1232; both have been restored as museums.

Despite the declining power of the later caliphs, Baghdad remained a great centre of trade and culture as long as the agricultural prosperity of Iraq continued. Its real downfall came when Hulagu the Mongol overran Mesopotamia and sacked Baghdad in 1258, killing the caliph Al-Musta'sim and, it is said, 800,000 of the inhabitants. The overthrow of the Abbasid government removed the authority which had secured the maintenance of the irrigation system and the protection of the cultivated land against nomadic tribesmen. With its political importance gone, its population decimated and the economic basis of its life destroyed, Baghdad never rose again above the status of a provincial city until the emergence of Iraq as an independent state after World War I. It remained subject to the Ilkhanid dynasty, successors of Hulagu, until 1340, when it achieved local independence under the Jalairids, who made some attempt to restore its fortunes; one notable group of buildings survives from this period, a mosque and college built in 1358 by Mirjan ibn Abdullah, governor of Baghdad, together with a fine vaulted khan which is now a museum of Islamic antiquities. In 1401 the city was sacked by the last of the Mongol invaders, Timur (Tamerlane), and in 1410 fell under the sway of the Black Sheep Turkomans, who gave way in 1469 to the White Sheep dynasty. They in turn were expelled by the Persians under Shah Ismail in 1508, and in 1534 Baghdad was taken for the first time by the Ottoman Turks under Suleiman the Magnificent. It was recaptured by the Persian Shah Abbas in 1623, but was recovered for Turkey by Murad IV in 1638; its frequent changes of allegiance were due in part to its geographical position between the two great empires, partly to the division of its inhabitants between the Shi'ah and the Sunni sects of Islam, the former favouring the Persian, the later the Turkish rule. During the 17th century a rapid succession of Turkish governors did little to restore the fortunes of Baghdad, depopulated and reduced to penury by two ruthless conquerors. The beginning of the 18th century, however, saw the appointment of two successive governors, father and son, Ahmed and Hassan Pasha, who reformed the administration by introducing the slave hierarchy of Circassian civil and military officials known as the Mamelukes, and raised the prestige of their capital until it controlled Mesopotamia from Basra to Mardin, owing only a formal allegiance to Istanbul. They were succeeded by a line of Mameluke governors until the abolition of the Mameluke system by Sultan Mahmud II in 1831. During the Mameluke period foreign, and notably British, influence became more marked in Baghdad. A British residency was established in the city in 1798, and in 1802 the resident was granted consular rank; under C. J. Rich (1808–21) and H. C. Rawlinson (1843–55) the prestige of the resident was second only to that of the governor. Baghdad was captured by British forces in 1917, and became the capital of the independent kingdom of Iraq in 1921. The city was the scene of an abortive revolt, inspired by anti-British feeling, in 1942, and of a successful *coup d'état* in 1958, when the monarchy was overthrown and Iraq became a republic. *See* IRAQ: *History; see* also Index references under "Baghdad" in the Index volume.

BAGHDAD PACT, a mutual security agreement among Turkey, Iraq, Iran, Pakistan and Great Britain, signed in 1955. The idea of organizing a middle eastern security system was not new. Prompted by Mussolini's threat in 1935, Turkey had formed the Sa'dabad pact (July 4, 1937), which included Turkey, Iraq, Iran and Afghanistan, but this soon became a dead letter. After World War II Britain hoped to rely on the Arab league (*q.v.*) and on bilateral treaties for the defense of the middle east. The Arab league, however, failed to create solidarity among the Arabs, and Great Britain reformulated its bilateral arrangements with the Arab states. Treaty relations with Jordan temporarily helped Britain to maintain an important strategic position; but its treaties with Egypt (1947) and Iraq (1948) proved abortive because of the rising tide of Arab nationalism and communist and anti-colonial propaganda.

The United States took increasing interest in the security of the middle east, as demonstrated by its participation with Britain and France in the tripartite declaration of May 25, 1950, regarding the sale of arms to Israel and the Arab states. The U.S. urged Britain to come to an understanding with Egypt, and this resulted in the Anglo-Egyptian agreement of 1954, by virtue of which Britain evacuated the Suez canal base. Egypt, however, failed to take part in organizing a regional security system, fearing that such an arrangement might be construed as the renewal of an alliance with Britain. Thus the middle east remained a weak spot in the fence with which the western powers hoped to surround the

U.S.S.R. Since Turkey and Greece had joined the North Atlantic Treaty organization (NATO), it was advocated that an arm of NATO be extended to the middle east from those states.

The initiative for approaching the Arab states to erect a security structure came from Turkey. Turkish attempts to enlist the co-operation of Egypt failed, but negotiations with Iraq, with which Turkey had entered into an agreement in 1946, were successful. The Turko-Iraqi (later called the Baghdad) pact was signed on Feb. 24, 1955. It was the first link in the "northern tier," later joined by Great Britain on April 5, Pakistan on Sept. 23 and Iran on Oct. 12.

The pact provided for mutual co-operation among its signatories in accordance with art. 51 of the United Nations charter. The member states pledged not to interfere in the internal affairs of one another, but agreed to co-ordinate their efforts in matters of defense and security. For this purpose a permanent council was provided, with a secretariat and a number of committees. The United States did not join the system but participated in various committees.

It was hoped that the other Arab countries would soon adhere to the pact, but Egypt immediately attacked it on the ground that it violated the Arab league security pact. Iraq replied that treaties with its neighbours did not contravene that pact and that Iraq had common interests with Turkey and Iran against communist infiltration no less than common interests with the other Arab countries against Israel. Iraq hoped that its central position between the northern tier countries and the southern Arab countries might permit it to initiate a more comprehensive regional security system co-ordinating the Baghdad pact with the Arab league security pact. The formation of rival federations in 1958—Egypt with Syria and Iraq with Jordan—seemed to frustrate this hope. After the overthrow of the Hashemite monarchy of Iraq later in the year by forces friendly to the United Arab Republic, Iraq ceased to participate in the pact and formally withdrew on March 24, 1959. The headquarters was meanwhile transferred from Baghdad to Ankara, Turk., and the name was changed to Central Treaty organization (CENTO). The United States in 1959 entered into bilateral defense agreements with Turkey, Iran and Pakistan. (M. Kı.)

BAGHDAD RAILWAY, the name given to the enterprise to connect Istanbul, the capital of the Ottoman Turkish empire, with the plains of Mesopotamia and the Persian gulf by railway. Of great importance for the economic development of the empire, it also aroused international rivalries in the years of tension preceding World War I as it threatened the monopoly previously held by the sea route between Europe, the middle east and India.

German activity on the enterprise began in 1888, when the Deutsche bank was granted a concession by the sultan Abdul-Hamid II to extend the existing line between Haidar Pasha and Ismid to Ankara, under the name of the Anatolian railway. The line to Ankara and another section of Eskisehir and Konya were completed in 1895–96. Great Britain, having recently acquired control over the Suez canal, was not interested.

The gradual extension of German influence in Turkey came about because the other powers were not concerned in the Baghdad railway. Russia notoriously wanted to break up the Ottoman empire; Great Britain thought mainly of protecting the Indian empire and the Persian gulf; and France was preoccupied with Syria. Germany thus appeared to the sultan to be the only country that would help him to develop the whole country and consolidate its economy, and in 1902 he granted to the Deutsche bank the concession to extend the existing Anatolian railway to Baghdad. Nevertheless, even in 1903 an agreement was reached for private British capital to participate in the enterprise, but the hostility of the British press and the British government's disapproval led to the abandonment of the proposal.

The railway thus became a joint Turko-German enterprise and the line was completed to Bulgurlu in 1904. The method of financing the construction was partly by a kilometric guarantee, and the Ottoman government's contribution was to have been secured by increases in the customs, for which the consent of the Ottoman Debt administration had to be obtained. As there was difficulty in obtaining this from France and Great Britain, the railway was partly financed by the issue of special bonds—the sale of which, however, was not allowed on the Paris Bourse. These difficulties and the cost of tunneling through the Taurus mountains made progress slow. By 1908, however, Turkish finances had sufficiently improved to pay the interest and sinking fund on the bonds. Moreover, the railways now running in Anatolia helped to increase internal trade and revenue. By 1912 the eastern section of the line was completed as far as the Euphrates.

As Germany grew more powerful, British opposition to the Baghdad railway increased. The revolution of the Young Turks (1908) made little difference to the attitude of the powers on the railway. Great Britain and France distrusted the Young Turks, while Germany supported them. Even so, the ground for an understanding between Great Britain, Germany and Turkey was prepared when the Deutsche bank, on behalf of the Baghdad Railway company, announced that it would not seek to extend the line beyond Baghdad to the gulf without Great Britain's approval. Subsequent negotiations led to a Franco-Turkish agreement in Feb. 1914 granting France railway concessions in northern Anatolia and to an Anglo-German agreement in June 1914 whereby the Baghdad railway between Basra and the gulf would not be built without the approval of the British, who were also to receive exclusive shipping rights on the Tigris and Euphrates. Thus a settlement between Great Britain, France, Germany and Turkey over the Baghdad railway was reached on the eve of World War I.

At the outbreak of war, the tunnels through the Taurus mountains were still not completed. By 1918, however, trains could run from the Bosporus to Nusaybin, only 300 mi. from Baghdad. The Turkish revolution after the war led to Turkey's taking over the old German concessions and to the creation in Anatolia of a Turkish National Railway system. The Arab succession states then took over the Syrian and Iraqi parts of the railway and in due course completed them. The railway thus runs from the Bosporus to the Persian gulf, its sections being operated by the states whose territory they cross. (M. P. P.)

BAGHLAN, a town in Kataghan province, Afghanistan, 35 mi. S. of Khanabad and about 3 mi. E. of the Kunduz river, lies about 1,700 ft. above sea level. Pop. (1960 est.) 20,000. It is a new industrial town and the centre of beet-sugar production in Afghanistan, being in the leading sugar-beet district of Afghan Turkistan. Cotton production and cotton manufacturing are also important in the region. (J. P. C. N. H.)

BAGLIONI, an Italian noble family dominant in Perugia between 1488 and 1534. Their ascendancy began with Malatesta Baglioni who helped to restore Perugia to the church after the death of Braccio (*q.v.*) in 1424 and was rewarded by the pope with the grant of Spello, to which other small communities (*e.g.*, Bettona and Bevagna) were subsequently added. This territorial power and wealth, increased by their pay as *condottieri*, enabled the Baglioni to prevail over their oldest rivals in Perugia, the Oddi, whom they expelled in 1488.

The Baglioni were typical members of their class, warlike and turbulent. They still took hire as *condottieri*, and a later Malatesta Baglioni betrayed his command as captain of the Florentines in 1530 by surrendering Florence to a besieging army in which others of the family were serving. The Baglioni were never formally created lords of Perugia, partly perhaps from deference to papal overlordship, which they publicly acknowledged before Julius II in 1506. They preferred to govern through a junta, the Dieci dell' Arbitrio, chosen from themselves and their clients. Under this regime, the chroniclers imply, the city suffered for many years from unchecked atrocity and crime. The family itself was rent by feuds and weakened by successive acts of domestic violence, the first of which, the "great betrayal" of 1500, was one of the bloodiest massacres in the dynastic annals of Italy. Even so the Perugians learned to regret the end of the reign of the Baglioni after Paul III banished them in 1534 and established direct papal rule.

The Baglioni continued to furnish captains of war until in the 17th century the several branches of the family declined or dis-

appeared.

See W. Heywood, *A History of Perugia* (1910). (P. J. J.)

BAGNACAVALLO (BARTOLOMMEO RAMENGHI) (1484–1542), Italian painter, whose work, considered to be inferior in point of design to some other productions of the school of Raphael, is distinguished by rich colouring and graceful drawing. He received the cognomen Bagnacavallo from the little village where he was born. He studied under Francia, and then in Rome as a pupil of Raphael, for whom he worked, with others, at the decoration of the gallery in the Vatican. His best works are the "Dispute of St. Augustine" and a "Madonna and Child" at Bologna.

BAGOAS, the Greek form of an Old Persian name often used for eunuchs. The best known of these became the confidential minister of Artaxerxes III. He was commander in chief of the Persian forces in the conquest of Egypt (343 B.C.) and gained wealth by selling back to the priests at an exorbitant price the sacred writings looted from the Egyptian temples. He worked in close partnership with Mentor of Rhodes and rose to such power that he became the real master of Persia, Artaxerxes doing nothing without his advice. In 338 or 337 B.C. he murdered Artaxerxes and all his sons save Arses, whom he placed on the throne. Two years later he murdered Arses and made a collateral, Darius III, king. When Darius asserted his independence, Bagoas attempted to poison him also, but the king had been warned and forced him to drink the poison himself. (*See* ARTAXERXES; DARIUS.)

The eunuch Bagoas, the supposed favourite of Alexander the Great, appears to be an invention of the Peripatetic philosopher Dicaearchus.

See, for the second Bagoas, W. W. Tarn, *Alexander the Great,* vol. ii, pp. 320–322 (1948). (J. M. M.-R.)

BAGOBO, a pagan tribe living on the lower slopes of Mt. Apo and the adjacent coast of southern Mindanao in the Philippines, numbering about 18,000 (1960s). At the head of the tribe is a warrior known as *datu.* Below him are petty *datus*—the rulers and judges of districts. Their power is great but they must operate within the customary law handed down by the ancestors. Next to the rulers are the magani, red-suited warriors who obtain valour by eating the hearts and livers of slain foes and who rank according to the number of lives to their credit. Workers in various crafts—weaving, metal casting, iron working—make up the next level of the hierarchy, all members of which are under the protection of guardian spirits. Below these are commoners and slaves. The Bagobo believes in a vast number of spirits, ranging from a creator, to guardian spirits, to shades of the dead, to beings who inhabit most natural objects. Each human being has multiple souls inhabiting various parts of the body. These may be induced to wander; hence soul snatching and soul catching become important in daily life. Many ceremonies are celebrated. Until prohibited by United States authorities, the most important of these was the yearly human sacrifice held to furnish companions for the souls of the dead. Daily activities are carried out with attention focused on the spirit world. Thus the manufacture of metal objects, the building of a house, the preparation of fields, planting and harvest, all require ceremonies and offerings. An unorganized priesthood directs these activities. Its members possess some knowledge of the treatment of sickness, and at times they act as mediums. Both sexes wear many ornaments in addition to hemp garments covered with intricate designs produced by the tie-and-dye method. Dry-land rice and Manila hemp are grown in sufficient quantity to allow some trade with the coast.

BAGPIPE, a wind instrument consisting of two or more pipes sounded by reeds to which wind is fed by arm pressure on a skin bag. The pipes are held in wooden sockets or stocks tied into the bag, which is inflated either by the mouth through a blowpipe provided with a leather nonreturn valve, or by bellows strapped to the body and worked by the arm not applying the pressure. The melodies are played upon the fingerholes of the melody pipe or chanter, while one or more other pipes or drones sound single notes carefully tuned against the chanter before performing by means of extendable joints. To articulate the melody and to reiterate notes, a piper employs the technique of gracing; *i.e.,* rapidly interpolating notes outside the melody to give an effect of detached notes in the latter.

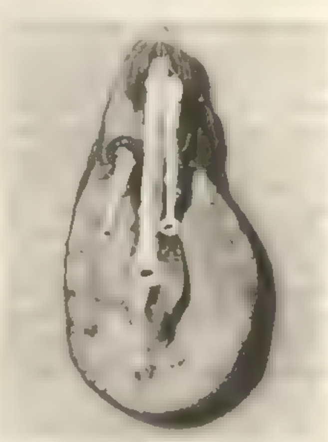
SCOTTISH HIGHLAND BAGPIPE, 19TH CENTURY

Bagpipes of numerous types, primitive and advanced, existed in Europe in the 13th century, and the instrument is alluded to in the 9th. Earlier evidence is less than is often claimed, and amounts to scarcely more than four Greek and Latin references of *c.* A.D. 100 (*e.g.,* Suetonius's mention of Nero as *utricularius*) and, without certainty, an Alexandrian terra cotta of *c.* 100 B.C. (at Berlin). Today the instrument's indigenous range extends across Europe to India. Primitive bagpipes typically employ for the bag a whole sheep- or goatskin less the hindquarters, and for the chanter two small cane pipes placed parallel, the one often sounding a drone or other accompaniment to the other. Most have cowhorn bells, being bag versions of hornpipes; they are found in north Africa, Arabia, the Aegean, the Caucasus and among the Marii in the Soviet Union. Other double chanters are made in east Europe (Serbia, Hungary, Ukraine, etc.) in a single piece of wood, keeping the cylindrical bore natural to cane pipes and the primitive single reeds of cane or elder. One of the two bores is a drone with a fingerhole for changing the note to the fourth below. There is also a separate bass drone tuned, like most bass drones, two octaves below the chanter keynote. The Bulgarian *gaida* and Czecho-Polish *dudy* (*koza*) have a single chanter, and in the *dudy* this carries a huge cowhorn bell, as does the drone.

The typical west European bagpipe has a conically bored chanter sounded by a double reed. Drones are cylindrical with single reeds, as in those described above. The Scottish highland bagpipe, now played widely over the world, has two tenor drones and a bass drone an octave below, and, as with many bagpipes and other folk instruments, its scale preserves traditional intervals foreign to learned musical systems. Once, like other European bagpipes, a pastoral and festive instrument, its military use with drums dates from the 18th century. The elaborate gracing technique is codified in tutors for the instrument. The Scottish lowland bagpipe, played *c.* 1750–1850, was bellows-blown, and had a softer sound, with the three drones in one stock. Akin to this were the bagpipes played up to the 18th century in Germany, the Netherlands and England, with two small parallel drones variously tuned to a fifth or an octave. These were also known in Ireland, but the modern two-droned Irish war-pipe is a modified highland bagpipe introduced *c.* 1905, followed by Henry Starck's "Brian Boru" model with three drones and keys on the chanter to extend its compass. The bagpipe of northwest Spain, *gaita gallega,* resembling the highland, usually has the bass drone only. The Breton *biniou* is a half-sized version played in duet with the pipe *bombarde* (*q.v.*) and is being supplanted by a copy of the highland bagpipe.



BY COURTESY OF THE METROPOLITAN MUSEUM OF ART, THE CROSBY BROWN COLLECTION OF MUSICAL INSTRUMENTS, 1889

FRENCH CORNEMUSE BAGPIPE, 18TH CENTURY

The cornemuse of central France is distinguished by a tenor drone held in the chanter stock beside the chanter; it is often bellows-blown and without bass drone. The Italian *zampogna* is unique, with two chanters, one for each hand, arranged for playing in harmony, often to accompany a species of *bombarde*; the chanters and two drones are held in one stock and all have double reeds.

The bellows-blown musette, fashionable in French society under Louis XIV, had a cylindrical chanter, beside which Jacques Hotteterre, *c.* 1750, placed a short stopped chanter with six keys giving notes above the main chanter compass. It employed a "shuttle" drone: a short cylinder bored with about 12 narrow channels variously connected in series to supply four drones, each sounded with a double reed and tuned or silenced by slider-keys moving in the slots through which the bores vented to the exterior. Partly offshoots of the musette are the British small-pipes (*c.* 1700) of which the bellows-blown Northumbrian small-pipe is played today. Its cylindrical chanter, with seven keys, is stopped at the bottom so that when all holes are closed it is silent, thus providing the means for true articulation and staccato. The four single-reed drones are in one stock and used three at a time. A complex species of similar date is the bellows-blown Irish union-pipe, with a chanter that is stopped on the knee both for staccato and to jump the reed to the higher octave, giving this bagpipe a melodic compass of two octaves. The three drones are held in one stock with three accompanying pipes or regulators. These resemble the chanter in bore and reeds, but are stopped below and have four or five keys struck with the edge of the player's right hand and arranged thereby to sound simple chords in support of the melody.

See A. Baines, *Bagpipes*, Pitt-Rivers Museum, Occasional Papers in Technology (1960); W. A. Cocks, "Bagpipe," *Grove's Dictionary of Music and Musicians*, 5th ed. (1954). (A. C. Ba.)

BAGRATION, PETR IVANOVICH, Prince (1765–1812), Russian officer, one of the famous generals of the Napoleonic wars. Descended from the noble Georgian family of the Bagratids, he was born at Kizlyar in the Chechen area north of the Caucasus. He entered the Russian army in 1782 and served for some years in the Caucasus. He was engaged in the siege of Ochakov (1788) and in the Polish campaign of 1794, being present at the taking of Warsaw and at the subsequent massacre. His merits were recognized by A. V. Suvorov, whom he accompanied in the Italian and Swiss campaign of 1799, winning distinction by the capture of Brescia. In the campaigns of 1805–07 he increased his reputation. With a small force of 6,000 men he successfully resisted the repeated attacks of Joachim Murat's 30,000 at Hollabrunn, and, though half his men fell, the retreat of the main army under M. I. Kutuzov was thereby secured. At Austerlitz he was engaged against the left wing of the French army, and at Eylau, Heilsberg and Friedland he fought with courage. In 1808, by a daring march across the frozen Gulf of Finland, he captured the Aaland Islands. In 1809 he commanded against the Turks in Bulgaria. In 1812 he commanded the 2nd army of the west, and, though defeated at Mogilev (July), rejoined the main army under Barclay de Tolly and led the left wing at Borodino (Sept. 7). There he received the wounds of which he died, at Simy, in the province of Vladimir, on the following Sept. 24 (new style; Sept. 12, old style). A monument was erected in his honour by the emperor Nicholas I on the battlefield of Borodino.

BAGUIO, CITY OF, capital of the subprovince of Benguet on the island of Luzon, Philippines. Pop. (1960) 27,251. The site was probably visited by Spaniards about 1829, and a small military contingent was stationed near there (La Trinidad); but the locality was little known until U.S. occupation of the islands began after the Spanish-American War (1898). Governor Taft and the early U.S. officials intended Baguio to be a summer capital, but the idea was never carried out by the Filipinos. Meanwhile it became a popular summer resort because of its location in the mountains at an elevation of 4,500 ft., with pine forests and other scenic features. Many hotels, cottages and homes have been built there to accommodate people from the lowlands during the hot season. Both the Philippine government and the U.S. embassy maintain accommodations there. The local administration is in the hands of a mayor and council. The city is about 160 mi. N. of Manila. To reach it a railway runs to a point beyond Dagupan. There are two automobile routes—the Baguio zigzag road and the Naguilian road. During the rainy season, from May or June until November, there is a heavy rainfall (annual mean, 181 in.), but the weather during the rest of the year is ideal. The native population consists largely of Igorots (*q.v.*); Episcopal missions in Baguio and elsewhere in Mountain province have done much to improve the condition of these non-Christian people. Baguio is an important gold-mining centre. It was occupied by the Japanese in Dec. 1941 and retaken by Allied forces in May 1945. John Hay base, a U.S. armed forces rest camp for the far east, is adjacent to Baguio. (An. C.)

BAGUIRMI, a former sultanate of north central Africa roughly conterminous with the modern prefecture of Chari-Baguirmi in the Republic of Chad (*q.v.*), lying southeast of Lake Chad, with an area of 33,591 sq.mi. The prefectural capital is Massénya.

The population ([1958 est.] 275,452) of Baguirmi is extremely mixed. In the southern and central sections of the country, particularly along the Shari river, live Negro tribes known as the Boua-Kara, Seroua, Babalia and Kotoko. However, the chief element of the population, the Baguirmese, consists of a mixture of Negroes, apparently of the Kenga tribe, and Arabs. Remnants of the Bulala, once the masters of the country, live south of Lake Fitri. The Baguirmese, who are divided into many small tribal groups (the Fulani, Arabs and Hausa), are Muslims, while the Negro tribes of the south, adhering to their traditional religious beliefs, are referred to as pagans. Many of the Baguirmese are skilled craftsmen who offer their textiles and metal work for sale in their local markets, which are held regularly in all towns and large villages. During the 19th century, when wars were frequent, the Baguirmese built large cities protected by walls.

The early history of the country is unknown. In the 15th century it was inhabited mainly by agricultural Negroes. During the 16th century it was invaded by tribes coming from the east (perhaps the Bulala or Kenga) who established themselves as its rulers. The Baguirmi dynasty appears to have been established in 1522; the rulers as well as many of their followers accepted Islam during the reign of the fourth sultan, Abdullah (about 1600). Europeans first learned about the existence of Baguirmi and the other powerful states of central Africa (Wadai, Bornu-Kanem) when Dixon Denham penetrated the Lake Chad region in 1823. Details became known particularly from Heinrich Barth, who was imprisoned by the Baguirmese in 1855, and from Gustav Nachtigal in 1872. During the 19th century Baguirmi was constantly at war with its neighbours, particularly Bornu and Wadai, and the various sultanates were temporary victors. Thus, in 1871 large sections of Baguirmi were tributary to the sultan of Wadai. All these states were rather wealthy as a result of the slave trade which they controlled. When in 1895 the French began to expand toward Lake Chad, most of these territories were subdued by Rabah Zubayr (*q.v.*). Sultan Gaourang of Baguirmi, whose power had been destroyed by Rabah, was willing to accept French protection and signed a treaty with Émile Gentil in 1897. The sultan agreed to supply French troops with food, and the autonomy of his people was recognized. After Rabah's defeat in April 1900, a new agreement was made in 1903. The sultan ceded his claim to the left bank of the Shari and renounced the right to levy slaves from his vassal people. In return he received 100 horses, 100 head of cattle and 1,000 thalers (silver coins). A final treaty was made in 1912, when part of the sultan's administration was placed more strongly under French control. During the administration of Governor Merllit, appointed in 1915, many of the sultan's former functions, such as jurisdiction over criminal cases and the collection of taxes, were taken over by the French. When Gaourang died in 1918 he was succeeded by Abd el-Kader, who in turn was followed by Youssouf in 1935.

BAHA AL-DIN (Beha ud-din or Bohaddin; Arabic Abu al-Mahasin Yusuf ibn Rafi' ibn Shaddad Baha' -al-Din) (1145–1234), Arab writer and statesman, author of the *Sirat Salah-al-Din* ("Life of Saladin"), was born at Mosul in 1145. He was first a teacher at Baghdad and then professor at Mosul. In 1187, after making the pilgrimage to Mecca, he entered the service of Saladin, who was waging war against the Christians in Palestine. Baha al-Din sought his favour by urging him to the vigorous prosecution of this war and presented him with his treatise on the laws and discipline of sacred war. He remained constantly attached to the person of the sultan, and was employed on various embassies and in departments of the civil government, being appointed judge of the army and judge of Jerusalem. After Saladin's death Baha al-Din remained the friend of his son Malik al-Zahir, who appointed him judge of Aleppo. There he employed some of his wealth in the foundation of colleges. When Malik al-Zahir died, his son Malik al-'Aziz was a minor, and Baha al-Din had the chief power in the regency, using it for the patronage of learning. He lived in retirement after the abdication of Malik al-'Aziz.

For an annotated Eng. trans. of *Sirat Salah-al-Din*, *see* C. W. Wilson and C. R. Conder, *The Life of Saladin*, in vol. xiii of the Library of the Palestine Pilgrims' Text Society (1897). For list of other extant works *see* C. Brockelmann, *Geschichte der arabischen Literatur*, vol. i, pp. 316 ff. (1898).

BAHA AL-DIN ZUHAYR (Abu al-Fadl Zuhair ibn Mohammed al-Muhallabi) (1186–1258), Arab poet at the court of the Ayyubid sultans of Egypt, was celebrated as the best writer of prose and verse and the best calligraphist of his time. His poetry consists mostly of panegyric and brilliant occasional verse distinguished for its elegance.

For the text of his poetry *see* E. H. Palmer, with Eng. verse trans. (1871). For his life *see* M. G. de Slane's Eng. trans. of Ibn Khallikan's biographical dictionary, vol. i, pp. 542–545 (1842).

BAHADUR SHAH I (1643–1712), Mogul emperor of India from 1707 to 1712, the second son of Aurangzeb (*q.v.*), was born at Burhanpur on Oct. 14, 1643. As Prince Muazzam he learned dissimulation during seven years of confinement by his suspicious father and deceived his younger brother, Azam Shah, into believing that he was not a contender for the throne. When Aurangzeb died in 1707, he forestalled Azam Shah in the seizure of the Agra treasuries and destroyed him at Jajau. In 1708, Kam Bakhsh, Aurangzeb's fifth son, was also defeated, near Hyderabad. Bahadur Shah maintained much of the power of the great Moguls. In 1707 and 1710, by force or conciliation he overcame unrest in Rajasthan, and between 1710 and 1712 a Sikh rising under "Guru" Banda was subdued though not extinguished. He died at Lahore on Feb. 27, 1712.

See William Irvine, *Later Mughals* (1922). (P. H.)

BAHADUR SHAH II (1775–1862), titular Mogul emperor of India from 1837 to 1858, was born on Oct. 24, 1775. A pensioner of the East India company, he had dignity without power, except over Indian imaginations, maintaining from his modest pension the palace, princelings and etiquette of the great emperors. As a poet and patron he presided over a flowering of Urdu literature and a revival of the arts. His court provided a school of manners for Hindustan, an embodiment of traditional culture. During the Indian mutiny (1857) he at first declined to lead the mutineers, but, unable to resist or escape, he became their rallying-point, even though they threatened his counselors and dignity. He succeeded in preventing Hindu-Muslim conflict within Delhi. In June he offered to open the city gates if granted honourable terms. Captured in September by Maj. William Stephen Raikes Hodson (*q.v.*) after the city's fall he was tried in 1858 and unjustly condemned. He was treated as a raree show before being exiled to Rangoon, Burma, where he died on Nov. 7, 1862.

See T. G. P. Spear, *Twilight of the Mughuls* (1951). (J. B. Ha.)

BAHA'I FAITH is the name of the religion founded in the 19th century by Mirza Husain 'Ali, known as Baha'u'llah (*q.v.*; "Glory of God"). Baha'u'llah was a follower of the Bab (*q.v.*) who, some years after the Bab's execution in 1850, claimed leadership of his community. In 1867 (or 1863) Baha'u'llah publicly proclaimed himself "him whom God should manifest," a divine spirit foretold by the Bab. The Baha'is believe Baha'u'llah to be the latest of a series of past and future divine manifestations that include Jesus, Mohammed, Zoroaster, and the Buddha. His teachings are believed to initiate a new dispensation for our age.

The cornerstone of Baha'i belief is the conviction that the Bab and Baha'u'llah are manifestations of God, who in his essence is unknowable. The Bab was the forerunner who announced a greater one to come. When Baha'u'llah proclaimed himself, the Bab's short dispensation was fulfilled. The third important figure in the Baha'i Faith was 'Abdu-l-Baha' ("Servant of the Glory"; 1844–1921), eldest son of Baha'u'llah and the perfect exemplar and infallible interpreter of his teachings. The writings and spoken words of these three central figures of the Baha'i Faith form its sacred literature.

Other important Baha'i tenets are the unity of religions and the unity of mankind. Baha'is believe all the founders of the great religions to have been manifestations of God and agents of a progressive divine plan for the education of the human race. Despite their apparent differences the great religions, according to Baha'is, teach an identical truth. Baha'u'llah's peculiar function was to overcome the disunity of religions and establish a universal faith. Similarly, the Baha'is believe in the brotherhood of all men and devote themselves to the abolition of racial, class, and religious prejudices. The great bulk of Baha'i teachings is concerned with social ethics; the faith has no priesthood and does not observe ritual forms in its worship.

The Baha'i world headquarters is in Haifa, Israel, and includes the shrine of the Bab, an archives building, and an administrative centre. From 1921 until his death the world community was headed by Shoghi Effendi Rabbani (1896–1957), who was appointed by his grandfather, 'Abdu-l-Baha', as guardian of the faith. Baha'is are organized into local and national spiritual assemblies, and through these bodies they conduct an extensive work of missions, publication, education, and general philanthropy. Worldwide leadership was assumed in 1963 by the Universal House of Justice, a nine-member body elected by members of the national spiritual assemblies.

During its early years the Baha'i Faith was confined almost exclusively to Iran. The religion was introduced to the Western world in the 1890s, and by 1920 the United States was its stronghold. There are Baha'i communities in approximately 300 separate states and dependencies, and Baha'i literature has been translated into about 370 languages. In the later 1960s there were four Baha'i houses of worship, in Frankfurt, Ger.; Sydney, Austr.; Kampala, Uganda; and Wilmette, Ill. *See* also Babism.

Bibliography.—*The Dawn Breakers; Nabil's Narrative of the Early Days of the Baha'i Revelation*, trans. by Shoghi Effendi, 2nd ed. (1953). The works of Baha'u'llah, the Bab, 'Abdu-l-Baha' and Shoghi Effendi Rabbani as well as numerous books about the faith are obtainable from the U.S. National Baha'i headquarters in Wilmette, Ill. The best source for current Baha'i activities is the biennial publication of the Baha'i Publishing Trust, Wilmette, Ill., *The Baha'i World*. (C. J. A.)

BAHAMAS, a self-governing British colony in the West Indies (*q.v.*), consisting of a chain of islands, islets, and reefs, which stretches for 760 mi. (1,223 km.) SE from Grand Bahama about 50 mi. (80 km.) off the east coast of Florida to Inagua off the eastern end of Cuba. The group comprises about 700 islands, about 30 of which are inhabited, and more than 2,000 cays (islets), with a total land surface of 4,406 sq.mi. (11,409 sq.km.). New Providence (58 sq.mi.), though one of the smaller islands, is the most important and contains the capital, Nassau (*q.v.*); the others are known collectively as the Out Islands, of which the larger and more populous are Andros (1,600 sq.mi. [4,144 sq.km.]), Great and Little Abaco (776 sq.mi.), Inagua (560 sq.mi.), Grand Bahama (430 sq.mi.), Eleuthera (164 sq.mi.), Cat, Acklins, Long, Exuma, Crooked, Mayaguana, San Salvador (Watling), Rum, the Biminis, Harbour, Spanish Wells, Ragged Island, and the Berry Islands.

The islands rise from two broad submarine banks that form an extension of the continental shelf off Florida; consequently the surrounding sea is generally shallow. The islands are, however,

separated into groups by several deep-water channels, the most pronounced of which—Crooked Island Passage—is used by ships sailing between North American east coast ports and the Panama Canal. Along the northeast margin of the archipelago, facing the open Atlantic, the sea floor descends rapidly to depths of more than 2,000 fathoms.

Relief and Geology.—The islands are for the most part flat and low. The highest elevation—about 400 ft. (122 m.)—is on Cat Island, but few islands rise much more than 200 ft. and some reach no more than 10 ft. above sea level. They are built principally of coralline and oölitic limestone of Pleistocene age—which provides useful building stone—and of wind-blown deposits. Active coral reefs fringe the coasts, which consist largely of coral sand beaches of dazzling whiteness. There are few stream-courses; the only permanent river is on Andros and the only large lake on Inagua. The soil is generally shallow and typically consists of reddish clay on higher, more freely drained land, and black, humus-rich loam and white sandy soil in low-lying areas.

Climate.—Lying within the subtropical high pressure belt and washed by the warm Gulf Stream in the north, the islands enjoy an equable climate with much sunshine. Together with the fine beaches the climate is the basis of the flourishing tourist trade. Temperature varies little through the year, from winter averages of 70°–75° F (21°–24° C) to summer averages of 80°–90° F (26°–32° C). The highest recorded temperature is 94° F and the lowest 51° F. Rainfall varies from 40 to 60 in. in the different islands and occurs, in association with southerly winds, mainly between May and September; hurricanes also occur occasionally at this season, usually in September. Hurricane Flora did much damage in 1963. The trade winds, from east and northeast, blow freshly during the winter dry season.

Vegetation and Animal Life.—The vegetation of the Bahamas has been greatly altered since the islands were discovered by Christopher Columbus. Probably at that time they were thickly wooded, but now considerable forests remain only on Abaco, Grand Bahama, Andros, Mayaguana, and some of the smaller islands. Caribbean pine dominates much of the woodland and provides lumber for domestic and export markets. Among native hardwoods lignum vitae, cedar, sabicu, madeira, and satinwood are commercially valuable. Many alien species have been introduced; some, such as logwood, have become naturalized and spread widely, while others, such as poinciana and casuarina, are planted as ornamentals. Low scrub covers extensive areas, and mangrove swamp fringes sheltered stretches of coast.

Animal life is comparatively scarce. Raccoons live on several islands and lizards, iguanas, and chameleons occur. The only large animals are feral horses, donkeys, cattle, and pigs, which abound on some of the remote islands, particularly Inagua. Birds are more numerous and more than 200 species and subspecies have been recorded. Preeminent among them are the flamingoes, which breed principally on Inagua and Andros. Marine life is varied and abundant, though less so than formerly. The West Indian or monk seal, now almost extinct, was once common. In 1688 Hans Sloane (*q.v.*) reported that "the Bahama Islands are filled with seals; sometimes fishers will catch 100 in a night." Turtles also have been much reduced in number, though the edible green turtle is still marketed locally and "tortoise shell" from the hawksbill is exported in small quantities. Fishing is a major occupation of the local population and is an increasingly popular sport among visiting tourists who are attracted by the wide variety of big-game fish. Crayfish and sponges are valuable export items, though the sponge industry has declined since the beds were attacked by disease in the 1930s.

History.—On Oct. 12 (old style), 1492, Christopher Columbus landed on an island called by its native inhabitants Guanahani. He renamed it San Salvador. Its actual identity is still in dispute, but it is generally believed to have been the island now known as Watling Island. The natives of the Bahamas, whom Columbus called Lucayans, were Arawak Indians. They also inhabited the Greater Antilles and were peaceful folk. Between 1492 and 1508 Spanish raiders carried off about 40,000 natives to work in the mines of Hispaniola (Haiti and the Dominican Republic), and the islands had become uninhabited more than a century before the first English settlement took place.

Though Columbus took formal possession of the islands with pomp and ceremony in the name of Spain, and though under the papal bull of demarcation of 1493 (and subsequent bulls) the islands were held to come within the Spanish sphere, the Spaniards made no attempt to settle them.

British interest began in 1629 when Charles I granted Sir Robert Heath, attorney general of England, territories in America including "Bahama and all other Isles and Islands lying southerly there or neare upon the foresayd continent. . . ." But there is no evidence that Heath made any effort to settle the Bahamas. In the 1640s Bermuda was troubled by religious disputes similar to those which at that time were disturbing England, and in 1644–45 a group of dissidents there sent two ships south to seek an island on which they might settle and worship as they pleased. In 1647 leadership in this enterprise was taken by Capt. William Sayle, who had twice been governor of Bermuda. In July of that year the Company of Eleutherian Adventurers was formed in London "for the Plantation of the Islands of Eleutheria, formerly called Buhama in America, and the Adjacent Islands." Sayle and about 70 prospective settlers, consisting of Bermuda Independents and some persons who had come from England, sailed from Bermuda for the Bahamas some time before October 1648. The place of their landing is uncertain, but modern belief is that they settled on Eleuthera, then known as Cigatoo. The settlement did not prosper. Some of the settlers returned to Bermuda as early as 1650. Sayle himself returned in 1657, being again appointed governor of Bermuda in 1658.

New Providence was first settled in 1656 by a fresh group of Bermudans. In 1663 South Carolina was granted by Charles II to eight of his friends as lords proprietors and they appointed Sayle as the first governor. Both Sayle and certain of those who had interested themselves in the settlement of New Providence independently drew the attention of the lords proprietors to the possibilities of the Bahama Islands, and in consequence the duke of Albemarle and five others acquired a grant of the islands from Charles II in 1670, and they accepted nominal responsibility for the civil government.

The proprietors did not take a very active interest in the settlement or development of the islands. In 1671 they appointed John Wentworth as the first governor, but thereby merely confirmed an election previously made by the existing settlers. Although elaborate instructions for the government of the colony were issued and a parliamentary system of government was instituted, the lot of both governors and settlers was far from easy. New Providence was more than once overrun by the Spaniards alone or in combination with the French, while any governor attempting to institute a semblance of law and order received short shrift from the settlers, who had found piracy the most lucrative profession. In 1684 the king himself intervened and required that a law be passed against the pirates, but apparently it had little effect.

Early in the 18th century official representations, supported by petitions from English merchants, were being made for direct crown control. Action was at last taken in 1717 when the lords proprietors surrendered the civil and military government to the king and leased the islands to Capt. Woodes Rogers, whom the king commissioned as the first royal governor. When he arrived in 1718, armed with the royal commission and a disciplined troop of soldiers, about 1,000 pirates surrendered and received the king's pardon, while eight of the unrepentant were hanged. His measures were so effective that in 1728 the colony was able to adopt the motto, *Expulsis piratis restituta commercia.*

Meanwhile, even in the troubled days of the lords proprietors there had been an attempt at peaceful settlement and in 1660 the present site of the capital was known as "Charles Towne" in honour of Charles II. Ever ready to pay lip service to the crown, these early settlers saw fit to change the name to Nassau when William and Mary came to the throne. With the restoration of order following the establishment of the royal government the settlers demanded an assembly. In 1729 after due inquiry Woodes

Rogers, acting under authority from the crown, issued a proclamation summoning a representative assembly and from then on, apart from the brief interruptions caused by foreign invasion, the government of the colony carried on in an orderly manner.

In 1776 Nassau was captured by the United States Navy, but after a few days the place was evacuated. In May 1782 the colony surrendered to Spain and, though it was restored to Britain by the Peace of Versailles in January 1783, it was brilliantly recaptured by Col. Andrew Devaux in April of that year before news of the treaty had been received. On the conclusion of the American Revolution many Loyalists emigrated from the U.S. to the Bahamas under very favourable terms offered by the crown. Among the newcomers was Lord Dunmore, formerly governor of New York and of Virginia, who served as governor of the Bahamas from 1786 to 1797. In 1787 the proprietors surrendered their remaining rights for £12,000.

The early years of the 19th century were largely occupied by the efforts of the assembly to thwart the attempts of the executive to ameliorate the conditions of the slaves, until the United Kingdom Emancipation Act came into force in the colony on Aug. 1, 1834. A Legislative Council was created by royal letters patent in 1841. The mid-19th century was taken up with a struggle for full recognition on the part of the dissenters against the established church, which was backed by the government and the upper classes; the struggle ended with disestablishment in 1869. From that time no incidents of particular political importance occurred until May 1963 when a conference was held in London to consider a new constitution for the islands. It was then agreed that the colony should have full internal self-government, the governor retaining reserved powers only for foreign affairs, defense, and internal security. The new constitution came into force on Jan. 7, 1964 (*see* also *Administration* below).

At a general election held on Jan. 10, 1967, Lynden Pindling's Negro Progressive Liberal Party and the mainly white United Bahamian Party (which had formed the previous government) each won 18 seats in the Bahamian House of Assembly. With the support of one of the two other successful candidates (the second was the speaker of the House of Assembly), Pindling formed the first Negro government of the colony. (The election had been called by the premier after it had been alleged that ministers were involved with U.S. criminal interests said to be concerned with a gambling casino on Grand Bahama.)

Population.—None of the original Arawak population survives. Following the first British settlement the population grew slowly until, with the arrival of the American Loyalists and their slaves, the white population, estimated at 1,760, was nearly doubled and the Negro population almost trebled. During the first half of the 20th century there was a marked increase in the population of New Providence and a slow decline in that of the Out Islands; by 1953 well over half the population was concentrated on New Providence. But after that year, with development of the tourist trade, population in the Out Islands increased. From 1931 to the 1960s the population of New Providence increased from about 20,000 to 80,000, while in the same period the Out Islands increased from 40,000 to 50,000. The total population of the colony (1963 census) was 130,220. About 85% of the total population is Negro.

Administration.—The colony achieved full internal self-government in January 1964 (see *History* above). The constitution then introduced provided for a governor, a Cabinet of at least eight members headed by a prime minister, and a bicameral legislature consisting of a Senate and a House of Assembly. The Senate has 15 members, eight appointed by the governor after consultation with the prime minister, five on the advice of the prime minister, and two on the advice of the leader of the opposition. The Senate has delaying powers over money and taxation bills. The House of Assembly consists of 38 elected members, of whom not less than 18 nor more than 22 were to represent the Out Islands, and not less than 16 nor more than 20 were to represent New Providence. Full adult suffrage was provided.

Education is compulsory between the ages of 5 and 14. There were about 150 government and 60 other elementary schools, 5 government and 10 other secondary schools in the mid-1960s.

Economic Development.—The earliest economic attraction of the Bahamas was as a source of slaves, tropical woods, turtles, and seals. The islands also served as a base for buccaneers harassing Spanish shipping. From the time of English settlement persistent attempts were made to develop plantation agriculture but with little success. The Loyalists who immigrated after the American Revolution stimulated the production of cotton, but the resultant prosperity did not last as pests destroyed the plants in 1788 and 1794 and the shallow soil was rapidly eroded by plantation methods of cultivation. Emancipation of the slaves in 1834 finally eliminated cotton production and an attempt to revive it in 1864 failed. In 1888 sisal hemp was introduced as a plantation crop but it also failed after a promising start. The Bahamas have in fact never had a staple item of export or permanent trade of any magnitude. During the American Civil War and later during the era of prohibition, the lucrative professions of blockade-running and bootlegging brought the islands two brief periods of unprecedented prosperity.

Agricultural production mainly serves local needs. Small holdings owned by peasant farmers produce a variety of vegetables and fruit, among which only tomatoes and okra are exported in quantity. Most of the livestock is owned by the peasant farmers, though there is a modern dairy and poultry farm at Hatchet Bay, Eleuthera. Forestry is an important activity on the islands of Grand Bahama, Abaco, and Andros where the pine forests are cut for lumber and, since 1956, for pulpwood. These products now constitute the Bahamas' most valuable export and are marketed respectively in Caribbean territories and Florida. Salt and crayfish are other leading exports.

The growing prosperity that the Bahamas have enjoyed since the beginning of the 20th century is due almost entirely to the development of the tourist trade. This began as early as 1860 with the building of the Royal Victoria Hotel at Nassau to accommodate winter visitors. Progress was slow at first but since 1945 the islands have become established as one of the premier resorts of the Caribbean area, particularly for visitors from the United States. In 1957 there were nearly 200,000 visitors from abroad, most of whom stayed in Nassau, though increasing interest was being shown in the more accessible of the Out Islands where there are many new hotels, clubs, and guesthouses. By the mid-1960s the number of visitors had risen to more than 800,000, of whom more than 500,000 went to Nassau and about 300,000 to the Out Islands.

Communications to and within the islands, both by sea and air, are good, and there are motor roads on New Providence, Eleuthera, and Grand Bahama. Asphalt roads were being built in many of the Out Islands in the mid-1960s. On Grand Bahama a deep-water harbour known as Freeport was being developed in the 1950s and 1960s in association with a tax-exempt industrial and commercial area and in 1964 its airport was modernized. Adjacent Lucaya, a beach resort with its gambling casino, marina, and 18-hole championship golf course, was a major tourist centre by the late 1960s. Freeport provides major bunkering facilities for shipping in the West Indies. International shipping and airlines from the United States, Canada, Great Britain, and elsewhere use the harbour and airport at Nassau and there are also internal services by sea and air to most of the Out Islands.

BAHA'U'LLAH (MIRZA HUSAIN 'ALI NURI) (1817–1892), the founder and central figure of the Baha'i Faith was born at Teheran, Persia, Nov. 12, 1817. In his youth he was an ardent supporter of the claims of the Bab (*q.v.*) and some years after the Bab's execution in 1850 became the leader of one of the factions into which his community split (*see* BABISM). In 1867 Baha'u'llah announced himself publicly to be "him whom God should mani-

fest," a divine figure whose coming had been foretold by the Bab. Baha'u'llah's followers believed him to have been a manifestation of God (a divine figure), the new revelation for that age, and Baha'u'llah in his writings and speeches repeatedly made reference to himself in terms that support their conviction.

Baha'u'llah's religious movement came into conflict with the Persian authorities who were disturbed by some of its revolutionary activities. He was banished to Baghdad in 1852 and from there was sent by the Turkish government first to Constantinople, then to Adrianople and finally to Akka (Acre) in Palestine, where he passed the remainder of his life in internment, dying in May 1892. The period after the announcement of the claim to be "him whom God should manifest" was marked by bitter controversy, even violence, between Baha'u'llah's followers and those of his half brother, Mirza Yahya, chosen by the Bab to be his successor. Akka became a centre of pilgrimage for Baha'is from Persia and America, to which the religion spread in the late 19th century.

Baha'u'llah's religious teachings were largely practical and ethical. He sought to establish a universal religion that urged social uplift and world peace. *See* BAHA'I FAITH. (C. J. A.)

BAHAWALPUR, a town, district, division and former princely state in West Pakistan, situated on the Sutlej, Panjnad and Indus rivers. The nawabs of Bahawalpur originally came from Sind and assumed independence after the first expulsion of Shah Shuja from Kabul in 1809. The state acceded to Pakistan on Oct. 7, 1947, and in 1955 became the basis of Bahawalpur division. The region which comprised Bahawalpur state can be divided longitudinally into three strips: (1) the western, called Sind, irrigated by flood water, is the most fertile, with numerous groves of date palms. It is an alluvial tract scored by deep depressions, remnants of old river courses. (2) The central section, called Pat, consists of fertile loam brought under cultivation by the Sutlej canals and yielding rich crops of wheat, cotton and sugar cane. (3) The eastern, called Rohi or Cholistan, lying beyond the irrigation boundary, is a barren sandy desert—an expansive wilderness of 13,000 sq.mi. It is separated from the central tract by a depression running parallel to the Sutlej. There are mounds of ruins of old settlements, called *Thers,* along its high banks. Wells are the only places in the desert where life is possible. The sources are so limited however that the inhabitants must be constantly on the move, and the subsoil water is salty. The people are mainly shepherds. A shrub known as khar (*Salsola griffithii*) is abundant and is burned to make carbonate of soda for soap and medicines. The average rainfall in the region is less than 5 in. a year.

BAHAWALPUR TOWN, formerly the capital of Bahawalpur state, and the headquarters of the district, lies on the main railway line from Peshawar to Karachi. Pop. (1961) 84,377. It is important for its location at the head of the Empress bridge, the only railway bridge over the Sutlej in West Pakistan. In A.D. 1748 Nawab Bahawalpur I raised a wall around the village of Nawab Mohammad Panah Khan Ghumrani and within it built the town which bears his name. It is situated on the riverside at a raised point in the midst of a flood-irrigated area. The town is surrounded by gardens and is encircled by a metaled road with avenues of trees and parks. Originally there were five gates, but three have been demolished. There are two main bazaars, one crossing the other. Noteworthy monuments include Bahawalgarh palace built by Nawab Bahawalpur II in 1791 and now used as government offices, and the residency and new palace built by Sir Sadiq Mohammad. The chief modern buildings include the central library, Dring stadium, Sadiq Egerton college, Jama-i-Abbasia (a renowned Muslim theological institute), and a large hospital. There is a zoological garden and museum and an Urdu academy. Bahawalpur has a large soap factory; cotton is woven and embroidery and pottery are made.

BAHAWALPUR DISTRICT. When the new district of Bahawalnagar was formed in 1953 Bahawalpur district was also reconstituted. In 1961 the population was 735,524 and the area was 9,587 sq.mi.

The district includes the central portion of the former state, with the districts of Bahawalnagar and Rahim Yar Khan, one at each end. The greater part is desert, inhabited by nomadic graziers. In the rest of the district agriculture and small-scale cottage industry are the principal economic activities. The language, known as Bahawalpuri, is identical with Multani. There are many shrines and ruins of old forts. Uch, about 30 mi. to the southwest of Bahawalpur, marks the site of an ancient town going back to Indo-Scythian times.

BAHAWALPUR DIVISION. On the integration of states and provinces into one unit of West Pakistan in 1955, Bahawalpur with Bahawalnagar and Rahim Yar Khan districts was made a division. Area 17,508 sq.mi. Pop. (1961) 2,574,066 with a density of 147.0 persons per square mile. About 80% of the cultivated area (approximately 4,000,000 ac.) is irrigated. Wheat, millets and sugar cane are the chief crops. (K. S. AD.)

BAHIA (BAÍA), an Atlantic state of Brazil, bounded north by the states of Piauí, Pernambuco, Alagôas and Sergipe, east by Sergipe and the Atlantic, south by Espírito Santo and Minas Gerais, and west by Goiás. Pop. (1960) 5,990,605. It ranks 6th in size among the states of Brazil with an area of 216,612 sq.mi. From east to west the state is divided into three distinct geographic regions: a narrow coastal plain characterized by a tropical rain forest (*mimosa*); a somewhat broader zone of rising, broken lands (*agreste*) suitable for a wide range of agriculture; and a semibarren plateau, about 3,000 ft. above sea level, which comprises most of the interior (*sertão*). The plateau is traversed from southwest to northeast by the São Francisco river. The climate varies from hot and humid along the coast to hot and dry throughout the interior. Cattle raising and mining are the principal industries in the *sertão*. The leading agricultural products of Bahia are cacao, produced near Ilhéus; sugar, grown in the Recôncavo, a fertile coastal district near the city of Salvador; and tobacco, raised in the *agreste* zone. Exports include cacao, sugar, tobacco, sisal fibre, castor beans, hides, mangabeira rubber, cabinet woods and rum. The bulk of the population, largely of mixed Negro and white racial origin, is located within 100 mi. of the coast. There is little immigration, while emigration to the industrial areas of the south tends to restrict the rate of population growth.

The capital, Salvador (*q.v.*) or Bahia (pop. [1960] 630,878), is the only large city in the state. Important towns are: Feira de Santana, inland from Salvador on the edge of the *sertão,* celebrated for its cattle fairs; Ilhéus, on the southern coast; Vitória da Conquista, on the highway to Minas Gerais and southern Brazil; Juàzeiro, on the São Francisco river; and Santo Amaro, in the Recôncavo. None of these towns exceeds 35,000 population. As a captaincy general from 1549, Bahia was the seat of the colonial government in Brazil for over 200 years. It retained its leading position as long as the colonial economy was based on sugar production.

Following the discovery of gold in Minas Gerais in 1695, the economic centre of the colony shifted to the south. The capital was transferred to Rio de Janeiro in 1763 and Bahia entered a gradual decline. It became a province of the empire in 1823 and a state in the republic in 1889. By the mid-20th century Bahia had not kept pace with the industrial and political growth of states to the south. In the late 1950s, however, with the inauguration of direct rail and highway connections to the south and the availability of electric power from the Paulo Afonso hydroelectric project, there were signs of appreciable increase in the rate of industrial development in Bahia. (R. E. P.)

BAHIA (city), Brazil: *see* SALVADOR.

BAHÍA BLANCA, city and third port of Argentina, located in the extreme southern part of the province of Buenos Aires. Pop. (1960) 136,137. Major rail systems and airlines as well as highways closely link it to the national capital of Buenos Aires, 400 mi. N.E. The bay of the same name forms a natural harbour, one of the best on the Argentine coast, for the city located 4 mi. upstream on the shallow Napostá river. The increased settlement and development of the area of the Colorado, Neuquén and Negro rivers (provinces of La Pampa, Neuquén and Río Negro) have contributed to the rapid growth of the port.

The city was founded in 1828 as a military outpost against Indian attacks and foreign encroachment on the unsettled southern

Argentinian coast. Its importance as a commercial centre began in 1885 when the first rail connection to Buenos Aires was completed. A grain industry was established in the last decades of the 19th century by immigrants, largely Italian. The port then became a commercial necessity for the region.

Bahía Blanca possesses modern port facilities. The naval station serves as the principal base of the Argentinian fleet, with dry docks capable of handling the largest battleships. The commercial facilities include subsidiary ports: Puerto Belgrano, developed by the Rosario-Puerto Belgrano railroad to handle exports; Puerto Ingeniero White, equipped with grain elevator capacity of 120,000 tons; and Puerto Galván, constructed by the Pacific railroad to handle the cargoes of wheat, wool and cattle from La Pampa. (Js. R. S.)

BAHMANI, the name of a Muslim sultanate in the Deccan (*q.v.*), India, was founded in 1347 by Ala ud-Din Hasan Bahman Shah supported by other military leaders in rebellion against the sultan of Delhi, Mohammed ibn Tughluq. It attained its apogee during the vizierate (1466–81) of Mahmud Gawan but dissolved into the five successor powers of Bijapur, Ahmednagar, Golconda, Berar and Bidar (*qq.v.*) between 1490 and 1518. Between 1347 and *c.* 1424 its capital was Ahsanabad (Gulbarga [*q.v.*]) and thereafter Mohammedabad (Bidar).

The Bahmani sultanate's main foes, in its efforts to extend itself securely over the Deccan tableland, were the Hindu rulers of Vijayanagar, Telingana and Orissa and the Muslim rulers of Khandesh, Malwa and Gujarat. In the north, by 1468 a *modus vivendi* with Malwa had been achieved. In the south, war with Vijayanagar over the fertile Krishna-Tungabhadra doab was endemic until Krishna Deva Raya succeeded, between 1510 and 1520, in incorporating the area in Vijayanagar. To the east, the Bahmanis often warred with the Hindu chiefs of Telingana who were usually allied to the rajas of Orissa. In the west, the Bahmanis were unable to control the coastal region beyond the Western Ghats, although Mahmud Gawan temporarily occupied Sangameshwar and Goa in 1471 and 1472.

The division of the Bahmani sultanate into four *taraf* (provinces) encouraged an autonomy which the reforms of Mahmud Gawan failed to combat. The continuing employment of Muslim adventurers from overseas often antagonized older Muslim settlers and disturbed the loyalty of the military classes toward the dynasty. The political domination of Muslim groups in a predominantly Hindu area was facilitated by mutual noninterference between the various religious communities. The Bahmani sultans often encouraged a fusion of Deccan cultures.

See H. K. Sherwani, *The Bahmanis of the Deccan* (1953). (P. H.)

BAHORUCO, a province in southwestern Dominican Republic (area, 532 sq.mi.), pop. (1960) 52,800. It extends from the high Sierra de Neiba in the north to the below sea level basin of Lake Enriquillo. Large, irrigated sugar cane plantations account for one-third of the cultivated area. Other significant crops are plantains, bananas, coffee, corn and beans. The province was created in 1943 from the western part of Barahona province and was later reduced in size by the formation of Independencia province. The capital city, Neiba (pop. [1960] 4,620), was founded at the beginning of the 18th century. (D. R. D.)

BAHR, HERMANN (1863–1934), Austrian author and playwright, whose keen interest in cultural movements makes his career a guide to literary developments in Austria during his lifetime, was born at Linz, Upper Austria, July 19, 1863, and after studying at Austrian and German universities settled in Vienna, where he worked on a number of newspapers.

Zur Kritik der Moderne (1890) and *Die Überwindung des Naturalismus* (1891) illustrate the first phase of his career in which he attempted to reconcile naturalism with romanticism. In 1907 he published *Wien*, a remarkable essay on the soul of Vienna, which, however, was banned. Later, under the influence of Maurice Maeterlinck, Bahr became a champion of mysticism and symbolism. His comedies, including *Wienerinnen* (1900), *Der Krampus* (1901) and *Das Konzert* (1909), are superficially amusing.

In 1903 Bahr was appointed director of the Deutsches Theater, Berlin, and in 1918 he was for a short time director of the Vienna Burgtheater. During World War I, under the influence of Catholicism, his novel *Himmelfahrt* ("The Ascension"; 1916) represented the staunchly Catholic school of thought in his country. His later critical works, which show his interest in the social effects of creative art, include *Dialog vom Marsyas* (1904) and *Expressionismus* (1914). Bahr died at Munich on Jan. 15, 1934.

See A. Fuchs, "H. Bahr," *Moderne österreichische Dichter* (1946); H. Kindermann, "H. Bahr," *Wegweiser durch die moderne Literatur in Österreich* (1954). (A. Gs.)

BAHRAICH, a municipal town, tehsil and district in the Fyzabad division of Uttar Pradesh, India. The town (3 sq.mi.; pop. [1961] 56,033) is 65 mi. N.W. of Lucknow. It is a place of pilgrimage, the tomb of the 11th-century warrior-saint Salar Masud Ghazi being visited by Muslims and Hindus alike. A large fair takes place every summer. The most prominent buildings are a Muslim monastery and the ruined palace of the nawabs of Oudh. The town is connected with Lucknow by the Northeastern railway metre-gauge line via Gonda (113 mi.). The continuation of the line northwestward to the Nepal frontier has made Bahraich a centre for trade with that country, mainly in grain, sugar, timber and tobacco. About 22% of Bahraich's population depends on commerce, 18% on nonagricultural production, 13% on cultivation and 5% on transport employment.

BAHRAICH DISTRICT (2,620 sq.mi.; pop. [1961] 1,499,929) is a wedge of territory between the Gogra river (*q.v.*) and Nepal, with which it has a common frontier of about 80 mi. It comprises (1) a central triangular highland zone projecting southeast from the Himalayas for about 50 mi.; (2) the great Gogra plain on the west, at an average of 40 ft. below the highland; and (3) on the east, the lesser basin of the Rapti river and its branch, the Bhalka. Within the district the forests and marshes of the southern Himalayan slopes give place to drier land; stream beds become deeper and typical Ganges plain country is reached in the south and southwest. The Gogra forms the district's southwestern boundary for 114 mi. Most of the population depends on farming and farm labour; the main crops are rice, maize, wheat, gram and sugar cane.

Little was known of the district before the half-legendary invasion of the Muslims under Salar Masud in A.D. 1033. They consolidated their rule there only in the 13th century, and the district was later held wholly or partly by the Raikwars (a Rajput clan), Nepal, Mogul Oudh and the British. (B. Sı.)

BAHRAIN (BAHREIN), an archipelago and independent sheikhdom under British protection, named after the largest island in the Gulf of Bahrain, an inlet of the Persian gulf, lies between the Qatar peninsula and the Hasa coast of Saudi Arabia. Bahrain Island extends 27 mi. north to south by 10 mi. east to west and is a low, generally level expanse of sand and bare rock, with Jebel Dukhan (450 ft.) the highest of a cluster of small rocky hills in the centre. Structurally the island is an upfold of limestone, marls and sandstone of Tertiary and Cretaceous age, similar to other oil-bearing structures in the Persian gulf area. Muharraq to the north and Sitra to the east are low-lying and are connected by causeway to the main island. Other islands are Umm An-Nasaan, Jidda and the Hawar group off Qatar. The climate is hot and rather humid in summer, but pleasant during the short winter season. Mean midday temperatures from May to September exceed 90° F. The scanty winter rain (3 in.) excludes agriculture save in the extreme north where copious fresh-water springs permit irrigation. The water probably originates in central and western Arabia.

The fauna of Bahrain is very limited in number and includes gazelles, hares, jerboas, mongooses and lizards. Among the birds (some of which are winter visitors) are ravens, sparrows, bulbuls, pigeons and flamingoes. The commonest domestic animals are donkeys, salukis and camels.

History.—Numerous ancient burial mounds in the northern and western upland slopes of Bahrain Island indicate early human habitation. These may be Sumerian. For a long time the archipelago was probably of local commercial and strategic value, but its recorded history started with the Portuguese occupation in 1507. In 1602 Arab subjects of the shah of Persia seized and

held Bahrain intermittently until 1783. In that year it was conquered by Arabs of the Ataiba or Utub tribe from the Arabian shore, whose paramount family, the Al-Khalifahs, became the independent sheikhs of Bahrain. Following a series of agreements between Great Britain and the ruling sheikhs from 1820 to 1892 the state became a British protectorate. In return for British support and protection the sheikh of Bahrain bound himself to refrain from "the prosecution of war, piracy or slavery" (1861); and in subsequent treaties and agreements the sheikhs agreed not to enter into any relationship with a foreign government (including restraint from granting fishing, pearling or oil concessions) without British consent. During the 19th century Britain intervened several times to defeat attempts to assert dominion over the islands by the sultan of Oman, the Wahhabis of Arabia, Turkey, Persia and Egypt, as well as to prevent piracy by the Bahrainis. Britain's special relationship with Bahrain was recognized by King ibn Sa'ud of Saudi Arabia in 1927. Iran has periodically advanced claims to sovereignty over Bahrain, but these were never recognized by Britain. British interest in Bahrain was first represented by the East India company, then by the government of British India.

Population and Social Conditions.—The land area of Bahrain is 231 sq.mi. and the population in 1959 was 143,213 including several thousand nationals of other Arab states, Iranians, Indians and Pakistanis. There are about 750 British and Americans, mostly employed in the oil industry. Manama, the capital, on Bahrain Island, had a population of 61,837 and Muharraq town 32,279. The Arab population is almost equally divided between the Sunni and Shi'a sects, but the ruling family and the wealthy classes are mainly Sunnis.

Until 1952, the sheikh's personal rule was virtually unquestioned, and local politics took the form of Sunni-Shi'a quarrels, but after that time there were demands for reforms in the legal code, administration and labour laws. Pan-Arab and antiwestern feeling increased the opposition to British influence and the traditional system of government. There is a British secretary of government and some British officials in the police and administration. Bahrain is the headquarters of the British political resident who represents the crown vis-à-vis the Arab states of the Persian gulf. There is a small British naval base at Khor Kaliya, and the civil airfield on Muharraq Island is also used by the Royal Air Force. Oil royalties enabled the government to provide extensive social services including free medical attention and free primary, secondary and technical education. Manama, Muharraq, Hidd and Rifa'a have municipal councils.

The Economy.—Dates, citrus fruit and irrigated vegetables are grown in the north of Bahrain Island. The traditional industries of dhow building, the manufacture of sail cloth and reed mats are still carried on. The once important pearl fishing fleet has dwindled from about 1,000 boats (1930) to about 30 in the early 1960s, largely because more profitable work is available. Of government revenue about 70% now comes from oil royalties and 30% from customs duties. Oil was first discovered in 1932, and since 1948 production has remained steady between 1,500,000 and 2,000,000 tons per year. The oil concession (55 years from 1940) is held by Bahrain Petroleum company, an American syndicate (consisting of Standard Oil of California and the Texas Oil corporation) registered in Canada, and technically a British company. There is a refinery with an annual capacity of 10,000,000 tons per year at Ahwali, refining local production and crude oil sent by underwater pipeline from the Aramco fields in Saudi Arabia. The tanker loading jetty is on the east of Sitra Island.

There is an important coastal trade in general cargo, and by virtue of its good harbour and early development Manama, which was declared a free transit port in 1958, is the main entrepôt for the Persian gulf. There are weekly steamer services to Karachi and Bombay. Muharraq international airport is the most important in the gulf. The main towns, villages, harbours and oil installations are connected by metaled roads, and there is a good bus service. Since World War I Bahrain's currency has been the Indian rupee. *See* also ARABIA.

BAHRAM (VARAHRAN, from older *Verethragna*, name of an Iranian deity), the name of six kings of Iran in the Sasanian period.

BAHRAM I (reigned A.D. 274–277; or 273–276 by T. Nöldeke's chronology, 271–274 by W. B. Henning's) was a son of Shapur I, under whom he governed the province of Gilan. His succession to his brother Ormizd I strengthened the Zoroastrian clergy, at whose instance in Bahram's third year the prophet Mani, founder of Manichaeism, was cruelly executed. Subsequent persecution of this sect involved also Christians and Buddhists. His characteristic radiate crown, known from coins, distinguishes Bahram in a rock-sculpture at Bishapur, though his name in the inscription was erased by Narses.

BAHRAM II (reigned A.D. 277–294; or 276–293 by Nöldeke's chronology, 274–291 by Henning's), son of Bahram I, soon had to defend his throne against a brother, Ormizd, viceroy of the eastern provinces. In A.D. 283, exploiting Bahram's preoccupations, the Roman emperor Carus invaded Mesopotamia unopposed and entered Ctesiphon. However Carus' mysterious death forced a Roman withdrawal, and, soon after, the overthrow of Ormizd made Bahram secure. Influential in this reign was the *mobed*, Kartir, a militant Zoroastrian reformer, honoured with the title "mobed of the deceased Varahran (I)." Numerous southern Persian rock-sculptures depict Bahram in his winged crown, and several include his queen (also figured on coins). Since female portraits are rare in Sasanian art, she must have been a major dynastic personage.

BAHRAM III (reigned A.D. 294; or 293 by Nöldeke's chronology, 291 by Henning's), Bahram II's son and successor, was designated Sakanshah (viceroy of Seistan) in youth to celebrate the father's eastern victory. Deposed after four months by a great-uncle, Narses, he is nevertheless shown by an inscription to have issued coins.

BAHRAM IV (reigned A.D. 388–399), a son of Shapur II, was Kermanshah (governor of Kerman) before succeeding his brother Shapur III. Kermanshah, the well-known city in Kurdistan, was named for him, as also Kermanshahan near Yazd. The partition of Armenia with Rome, often ascribed to Bahram, is better dated to A.D. 387.

BAHRAM V (A.D. 420–438), surnamed GOR, "the Wild Ass," was celebrated in literature, art and folklore for his chivalry, romantic adventures, and the huntsmanship recalled in Edward Fitzgerald's *Rubaiyat* (1859). Educated at the court of al-Mundhir, Lakhmid Arab king of Hira, whose military support gained him the throne, Bahram tended to delegate administrative cares to his minister Mihr-Narseh, whose zealotry motivated both persecutions deplored by Christian writers and benefactions in his home province, Fars (described by al-Tabari and a surviving Pahlavi inscription). An inconclusive war with Byzantium (421–422) was soon ended. Bahram's martial qualities were unimpaired by gracious living; in 427 he crushed an invasion of Khurasan by the Hephthalites (*q.v.*), extending his influence into central Asia, where his portrait survived for centuries on the coinage of Bukhara.

For BAHRAM VI *see* BAHRAM CHOBIN.

BIBLIOGRAPHY.—A. Christensen, *L'Iran sous les Sassanides* (1936); *Corpus Inscriptionum Iranicarum* (1957–); Norman H. Baynes, *Byzantine Studies and Other Essays*, pp. 186 ff. (1955). (A. D. H. B.)

BAHRAM CHOBIN (perhaps "Bahram the Javelin") (6th century A.D.), Persian general and head of the house of Mihran at Rayy, by attaining the throne as Bahram VI (A.D. 590–591) performed a feat exceptional for one not of Sasanian—though claiming Arsacid—royal blood. Prominent as master of the household (*darigbed*) in Ormizd IV's Byzantine wars, Bahram received the supreme command in Khurasan, repelling a Turkish invasion. Re-

verting to the west, he sustained a defeat and was harshly disgraced by Ormizd. Still sure of his army, Bahram rebelled; in the disorder Ormizd was assassinated by another hand. Khosrau II, Ormizd's successor, marched against the irreconcilable general, but the royal troops mutinied, and Khosrau fled to the Byzantines. Bahram then proclaimed himself king, but was never secure. In 591, with Byzantine support, Khosrau triumphed and regained the throne. Bahram escaped to Turkistan, to perish by assassination. His colourful career became the subject of a Middle-Persian popular romance. (A. D. H. B.)

BAHR EL GHAZAL (Bahr al Ghazal), a province of the Republic of the Sudan. Area 82,529 sq.mi. Pop. (1956) 991,022. The province does not coincide with the whole Bahr el Ghazal river system but only with the Lol, Jur and Tonj basins, south of the Bahr al 'Arab, north of western Equatoria, and west of the Sudd, of which a part is included.

The whole area west of the Bahr el Jebel consists of a plateau tilted gently northeastward from the Congo watershed at a height of 2,000–2,500 ft. to where at about 1,000 ft. it passes under the level clays of the Sudd basin of which Lower Bahr el Ghazal is a part. The basement platform of ancient gneiss and schists with granitic inselberg (*q.v.*) is exposed in hills and river beds, but its name of "Ironstone plateau" is derived from its thick outer covering of "hard-pan" and ferruginous earths formed in the laterite soils and now patchily covered with more recent red loams and sands, masking any possible mineral wealth. There are potential copper deposits at Hufrat an Nahas on the upper Bahr al 'Arab.

The temperatures reach their highest and lowest (100° and 60° F.) during the dry season from November to March and otherwise range between 70° and 85° F. The rainfall is sufficient for woodland or long-grass savanna. However the grass is burned to extend cultivation, to improve grazing or to destroy the tsetse fly; this prevents tree growth and destroys timber. Sudan mahogany (*Kaya senegalensis*) and shea butter trees are among the patches that survive, and Wau is a centre of conservation services as well as of sawmills exploiting *Kaya* and other timber. Game abounds and includes elephant, giraffe, lion and buffalo, as well as many large and small antelope. The Sudd region of the northeast, especially Lake Ambadi, teems with waterfowl, and some rare swamp birds like the shoebill stork (*Balaeniceps rex*) are common there.

Of the population, 92% are Nilotes (*q.v.*), chiefly the Dinka, 875,000 of whom raise cattle in the grass flats, swamps and lower valleys, migrating seasonally to and from the river line. About 10% are fishers, crocodile and hippopotamus hunters. Women and children grow millet, bananas and gourds near the permanent villages. The tribes of the plateau and upper valleys are Sudanics, of the N'dogo, Bongo (*q.v.*) and Baka, who beside hunting and collecting fruits, seeds and wild honey for trading, grow millet, sesame and peanuts, cassava and sweet potatoes. There are a few Arab Sudanese (officials, clerks and traders) and foreigners. Trade is undeveloped, though Bahr el Ghazal hides and skins are prominent in the Sudan's export of these goods. Oilseeds, timber and wood fuel, bananas and some ivory are also shipped down-river.

The Bahr el Ghazal was first penetrated by Arab slavers and ivory hunters. Their old trading posts are now district centres, but of the four rural headquarters with councils and commissioners only Wau (pop. 8,009), the provincial capital, can be considered a town. Rumbek (2,944) has the largest secondary school in southern Sudan but illiteracy is widespread throughout the province. The other rural district councils are Aweil and Tonj.

From 1936 to 1956 the Bahr el Ghazal territory was joined to Equatoria, and under the governor in Juba. Progress in direct communications with Khartoum through development of roads and motor transport and through the airport at Wau made it more practical in the independent Sudan to have a governor in Wau directly responsible to the government for the mainly Nilotic peoples of Bahr el Ghazal. *See* also Sudan, Republic of the.

BAHR EL GHAZAL RIVER (Gazelle river), the chief western affluent of the Nile, 445 miles long, joins the Upper Nile (Bahr el Jebel) in latitude 9° 30′ N., longitude 30° 30′ E., through Lake No. It then flows eastward as the al Bahr al Abyad, or White Nile. Vaguely known to Greek geographers who thought it to be the source of the Nile, the Bahr el Ghazal was mapped as early as 1772 by J. B. d'Anville, and played an outstanding part both in exploration and in Sudanese history.

The large catchment area (328,750 sq.mi.) extends from south Darfur and Kordofan to the Republic of the Congo (former Belgian Congo) border, and from the frontier of the Central African Republic (Shari watershed) almost to the Bahr el Jebel, from which it is separated first by a narrow strip of plateau, and then by low, grassy plains and swamps of uncertain drainage direction, part of the Sudd. The river is called the Bahr el Ghazal only after it has been joined by its main affluents. These are the Jur, the Tonj (both from the south) and the Bahr al 'Arab (from the north and west). Northern tributaries from the Darfur hills are intermittent, some never reaching their main stream on the surface at all. Only the main Bahr al 'Arab and Lol are fed from areas with rainfall over 35 in., and also retain more water, the Lol being largely permanent as the Jur (or Sue) and the Tonj. These cut well-marked valleys across the southwestern Ironstone plateau before entering the clay plain of Lower Bahr el Ghazal. At their sources, the rainy season with about 50 in. annual precipitation lasts from March to November and rocks are mainly impermeable. Hence the largest rivers are permanent, though variable in depth with rapids and shoals, and attract settlement for both water supply and fish, an important food in the protein-deficient south. The smaller affluents, from areas of more rapid runoff are fished out early in the dry season.

The Jur is navigable for 170 mi. for shallow-draft steamers up to Wau, the provincial capital (pop. [1956] 8,009), from July to October or November. When Wau is inaccessible by river, the head of navigation is at Mashra'ar Raqq, on a backwater south of the Jur mouth, a famous centre for the traders and explorers in the 18th and 19th centuries. The total navigable distance on the Bahr el Ghazal above Lake No is 305 mi. to Wau, or 144 mi. to the Mashra'ar Raqq.

The Jur mouth is actually Lake Ambadi, 10 mi. by 1 mi. at low river, but of vast size in the flood, though with only a 3-ft. increase of depth, a characteristic of the Sudd region. Although free from papyrus and ambatch thickets, Lake Ambadi like Lake No is encumbered with reeds, and since 1957 with the water hyacinth. Evaporation and transpiration by aquatics and swamp plants so reduce the water that in spite of its huge catchment area the Bahr el Ghazal discharges at Lake No a maximum of about 1,800 cu.ft. per second and often nothing at all. *See* also Nile.

See H. E. Hurst, *The Nile* (1952), *A Short Account of the Nile and Its Basin* (1925), and with P. Phillips *et al.*, *The Nile Basin* (periodical, 1931–). (M. T. P.)

BAHYA BEN JOSEPH IBN PAKUDA, Jewish religious philosopher, was active in Muslim Spain in the second half of the 11th century. Around 1080 he wrote, in Arabic, a *Guidebook to the Duties of the Heart*. Practical rather than speculative in purpose, clear in language and filled with examples, the book, in a 12th-century Hebrew translation, became a widely read classic of Jewish philosophic and devotional literature.

Critical of his predecessors who, of the two requirements of religion, had emphasized the "duties of the body" to the neglect of the "duties of the heart," Bahya wrote his book to restore the proper balance. The "duties of the body" are for him those obligations which manifest themselves in man's outward actions, namely in religious ritual and ethical practice, while the "duties of the heart" are those obligations which manifest themselves in the state of his soul, namely in his attitudes and intentions. Each of the ten chapters of the book is devoted to one fundamental duty of the heart. Considering correct belief as the foundation of religion, Bahya begins by discussing the unity of God. He proceeds to an examination of the world which exhibits God's goodness, the gratitude for which leads to his service. This service should be accompanied by trust in God, sincerity, humility, re-

pentance, self-examination and asceticism. The goal is the love of God which consists of the soul's turning from the world and attaching itself to its creator.

Bahya supports his discussion with citations from scriptural and rabbinic authorities and with rational argument. He draws freely upon relevant non-Jewish sources. An English translation of the work was made by Moses Hyamson. (A. H.)

BAÍA (state), Brazil: *see* BAHIA.

BAIAE (modern BAIA), 10 mi. W. of Naples, Italy, an ancient city of Campania, on a bay on the west coast of the Gulf of Puteoli (Pozzuoli), traditionally named after Baios, helmsman of Ulysses. Perhaps originally the harbour of Cumae (*q.v.*), it was in early Roman times called Aquae Cumanae because of its curative sulfur springs. Its mild climate and luxuriant vegetation made it a fashionable watering place during the later years of the Roman republic and under the empire, and by the 1st century A.D. it was as large as Puteoli. Many magnificent villas were built there; *e.g.*, those of Julius Caesar (probably on the ridge above the 16th-century castle) and Nero (probably on the castle site). The emperor Hadrian died in Caesar's villa in A.D. 138. Extensive remains of bathing establishments include three large domed buildings, popularly called temples. Since the level of the sea has risen about 12 ft., part of the ancient site is now submerged. Baiae was devastated by the Saracens in the 8th century A.D. and entirely deserted because of malaria in 1500. South of Baiae was the resort of Bauli (perhaps the modern Bacoli), where Pompey and the orator Q. Hortensius possessed villas, the latter the scene of the dialogue in Cicero's *Academica Priora*. Later this villa became imperial property and was the scene of Agrippina's murder by Nero. In the neighbourhood are remains of a small theatre, called the tomb of Agrippina, and of two great water reservoirs (Cento Camerelle and Piscina Mirabile).

See A. Maiuri, *The Phlegraean Fields*, Eng. trans. (1947). (H. H. SD.)

BAIA MARE (Hung. NAGYBÁNYA), a town in northwestern Rumania, chief town of Maramureș region, is situated 34 mi. S.E. of Satu Mare. Surrounded by mountains, it is a mining and industrial centre whose population rose from 12,780 in 1921 to 46,312 in 1963. It was founded in the 12th century by Saxon immigrants, when it was known as Neustadt. Zinc, lead, gold and silver were extracted there. Hungarian until World War I, Baia-Mare became Rumanian in 1918. It was reoccupied by Hungary from 1940 to 1945. After World War II production increased with planned industrialization. Apart from zinc and lead smelting plants, sulfuric acid and synthetic fertilizers are produced. Until 1948 Baia Mare was the see of a Uniate bishop.

BAÏF, JEAN ANTOINE DE (1532–1589), French poet, was the most learned member of the Pléiade (*q.v.*). Born at Venice, Italy, in 1532, the natural son of Lazare de Baïf, (then French ambassador there, whose elegant Latin verse and translation of *Electra* [1537] won him fame as a humanist), the son received a classical education. In 1547 he went with Pierre de Ronsard to study under Jean Daurat at the Collège de Coqueret, Paris, where they planned, with Joachim du Bellay, to transform French poetry by imitating the ancients and the Italians. To this program Baïf contributed two collections of Petrarchan sonnets and epicurean lyrics, *Les Amours* (1552) and *L'Amour de Francine* (1555). In 1567 *Le Brave*, Baïf's lively modernized adaptation of Plautus' *Miles Gloriosus*, was played at court and published.

Baïf enjoyed royal favour and received pensions and benefices from Charles IX and Henry III. His *Euvres en rime* (1573) reveal great erudition: Greek (especially Alexandrian), Latin, neo-Latin and Italian models are imitated for mythological poems, eclogues, epigrams and sonnets. His verse translations include Terence's *Eunuchus* and Sophocles' *Antigone*. Baïf was a versatile, inventive poet who was always experimenting: for instance, he invented and used a system of phonetic spelling. With the musician J. Thibault de Courville, who gave him the idea of composing quantitative verses modeled on Greek metres and setting them to music, Baïf founded an *Académie de poésie et de musique* to promote certain Platonic theories on the union of poetry and music. Charles IX granted letters patent in 1570 and attended the concerts and discussions, as did Henry III, in whose reign it was called the *Académie du Palais*.

Baïf's metrical inventions included a *vers baïfin* of 15 syllables. His theories were exemplified in *Etrénes de poézie fransoèze an vers mezurés* (1574), without music, and *Chansonnettes mesurées* (1586), with music by Jacques Mauduit. He also translated the Psalms into quantitative verse, for which Mauduit and C. Le Jeune composed music. Baïf's *Carmina* (1577) are Latin poems. His *Mimes, enseignemens et proverbes* (1576; augmented 1581, 1597) are considered his most original work; some of the *mimes* are outspoken satires on the unhappy conditions produced by the religious wars. He died in Paris in Oct. 1589.

Like Ronsard, Baïf is a personal poet and gives autobiographical information. His misfortune was to have a noble passion for poetry without the highest poetic gifts. His best quality is a talent for vivid realistic description, particularly in scenes of country life and in satire. Baïf's works were edited by C. Marty-Laveaux (Paris, 1881–90).

BAIGA, a tribe of India, about 30,000 people in the 1960s, in Mandla and adjacent districts of Madhya Pradesh. Baigas speak various Indo-Aryan dialects of Chhattisgarhi and Bundeli, as do their peasant and tribal neighbours. They appear allied in physique with other tribes and low Hindu castes of the region. Historically, Baigas seem to have retreated from the denser forest and are now mainly settled in remote valleys and hills. There they prefer to practise shifting agriculture under mythical sanction; they use iron axes and hoes, but not plows, cutting and burning fresh millet patches in the jungle every two or three years, as far as permitted under governmental regulation. Hunting, fishing and collecting of forest products are also main sources of subsistence. Mahua flower liquor is much valued. Villages are of wattle and thatch in a three-sided plan. The tribal costume is an abbreviated version of regional Hindu peasant costume, although Baigas are noted for their proscription of the Hindu custom of cleansing with water after defecation. The tribe has its own priesthood and a varied pantheon of gods whose names are Hindu but whose personal traits and good humour are unique.

Baigas have a cultural identity but are divided socially into at least 11 territorial subtribes which do not intermarry freely. Descent is traced patrilineally through indigenous localized lineages and also through a system of nonlocalized clans evidently imitated from surrounding peoples. Kinship usages generally resemble those of peasants of middle India, except that cross-cousins on both sides are approved for marriage.

See V. Elwin, *The Baiga* (1939); D. S. Nag, *Tribal Economy* (1958); J. H. Hutton, *Caste in India*, 4th ed. (1963). (M. MA.)

BAIKAL, LAKE (OZERO BAYKAL), lies in eastern Siberia, within the Buryat Autonomous Soviet Socialist Republic, U.S.S.R., and Irkutsk *oblast*. It is the third largest lake of the U.S.S.R. and the eighth largest in the world, with an area of 12,162 sq.mi. The outline of the lake is long and narrow, its length (roughly northeast to southwest) being 395 mi. and its width varying from 15 to 49 mi. Its surface is 1,486 ft. above sea level. The lake is walled in by mountains, extensions of the Sayan mountains. Along the northwestern shore are the Primorski and Baikal ranges and along the southeastern lie the Khamar-Daban, Ulan-Burgasy and Barguzinski ranges, separated by the major valleys of the Selenga and Barguzin rivers. There are 18 islands in the lake, the biggest being Olkhon Island, the steep mountain sides of which rise to 4,186 ft. The others form the Malyye Ushkani island group off the Svyatoi Nos peninsula, which juts out into the lake from the southeastern shore. Transbaikalia (Zabaykalye) is the region between Lake Baikal and the Upper Amur river.

The origins of the lake are tectonic, the deep depression in which it lies being formed by faulting. The fringing mountains rise up steeply to a maximum height of 8,445 ft., while the lake has a maximum depth of 5,715 ft., making it the deepest in the

world (in April 1960, it was announced that new soundings had not confirmed the formerly believed maximum depth of 5,714 ft.). The lake bottom can be divided into three basins. The most south westerly, which reaches 4,528 ft. deep, was formed during the Upper Jurassic period; the central basin, between the Selenga delta and Svyatoi Nos, is the deepest and was formed in the Tertiary period, at which time the first basin was deepened; the third basin, up to 2,992 ft. deep was formed at the very end of the Tertiary, when the two earlier basins sank still farther. Movement is still continuing and earthquakes occur around the lake. In the 1862 earthquake over 73 sq.mi. of the Selenga delta sank beneath the lake to form the Proval gulf.

Lake Baikal has 336 tributary rivers, several of which are of considerable size—the Selenga, Barguzin and Upper Angara. These larger rivers have formed sizable deltas in the lake, the only significant breaks in the mountain walls along the 1,240-mi.-long shoreline. The outlet for the lake is the Angara, a tributary of the Yenisei. A large hydroelectric station was completed in 1956 on the Angara at Irkutsk, about 36 mi. below the lake.

Baikal is characterized by low annual average temperatures of the surface water, 40° F. in the south, 37° F. in central Baikal. Maximum temperatures occur in September and only in rare years pass 50° F. Below about 700 ft. the water temperature remains constant at about 39° F. Until the lake surface freezes over in late December Baikal has a marked warming influence on the climate of the vicinity, up to 18° warmer than Irkutsk. Similarly, the lake has a cooling influence in summer.

The lake is remarkable for the richness of its fauna and flora. Of the 1,700 species identified there, 1,083 are not found anywhere else in the world. These include 773 plant species, 210 protozoa and 710 other animal species. The lake is rich in plankton. The one mammal is the Baikal seal (*Phoca sibirica*). The genus of amphipod crustaceans (*Gammarus*) or sand hoppers is represented by 292 species and 66 subspecies.

Fishing is important, although the catching of certain fish is now limited, and in the case of the sturgeon prohibited. The *omul* of the salmon family makes up about half the annual catch of 100,000 tons. Baikal is used for navigation and timber rafting, but losses of timber are high. This is attributed largely to the frequent severe storms on the lake, together with the lack of sheltered harbours. Most river mouths have bars which impede navigation. There are steamer services between the lake ports of Listvyanka, Babushkin, Ust-Barguzin and Nizhne-Angarsk. In winter, ice roads usable by vehicles are established across the lake. The trans-Siberian railway and a motor road follow the shore at the southern end of the lake. (R. A. F.)

BAIKIE, WILLIAM BALFOUR (1825–1864), Scottish explorer, naturalist and philologist, whose travels into central and northern Nigeria helped to open up the country to British trade. He was born at Kirkwall, Orkney Islands, on Aug. 27, 1825. After studying medicine at Edinburgh, he joined the navy as an assistant surgeon and was invited to take part in the Niger expedition, sponsored by Macgregor Laird with government support, which was to sail up the Benue river and attempt to make contact with the explorer Heinrich Barth (*q.v.*). On Capt. John Beecroft's death at Fernando Po, Baikie took command of the expedition and penetrated 250 mi. further up the Benue than anyone previously. In 1857 he returned, as British consul, to explore the Niger in the steamer "Dayspring." She was wrecked in the rapids above Jebba and although the expedition broke up Baikie continued his work. At Lokoja, at the confluence of the Niger and the Benue, he founded a settlement for trading on the rivers and overland. There Baikie ministered to medical and all other needs, compiled various African vocabularies and translated parts of the Bible and Prayer Book into Hausa. In 1862 he made a journey to Bida, Zaria and Kano, a distance of about 250 mi. Baikie's early writings were on Orkney and throughout his life he contributed to learned journals. He recorded his first expedition in *Narrative of an Exploring Voyage up the Rivers Kwo'ra and Binue . . . in 1854* (1856). He died at Sierra Leone en route for home leave on Dec. 12, 1864. (R. M. P.)

BAIL, in Anglo-American law, refers to the procedure by which a judge or magistrate sets at liberty one who has been arrested and imprisoned in connection with a legal matter, criminal or civil, upon receipt of security to ensure the released prisoner's later appearance in court for further proceedings in the matter. The security itself is also called bail. The principal use of bail is to secure the release, pending trial, of one arrested and charged with a criminal offense. Its use in civil cases has diminished along with the decline of imprisonment for debt; but bail is used to secure the release of an alien pending deportation proceedings or of a juvenile awaiting a hearing on a petition charging delinquency. So too a material witness, imprisoned to ensure his presence at a trial, may be released upon furnishing bail. (For the various means of furnishing bail, and for the relationship of the arrested person to his sureties, *see* RECOGNIZANCE.)

United States.—Three-fourths of the states have constitutional provisions guaranteeing that "all persons are bailable by sufficient sureties except for capital offenses where the proof is evident or the presumption great"; in the other states and in the federal system, where the constitution grants no such absolute right to bail, the judicial officers who administer bail have a greater discretion regarding the granting of bail in particular cases. In addition the U.S. constitution and the constitutions of almost all states contain provisions forbidding excessive bail; *i.e.*, requiring bail, when granted, to be fixed at a reasonable amount. *See* also BILL OF RIGHTS, UNITED STATES.

The purposes of bail pending trial in criminal cases are to avoid inflicting punishment upon an innocent person (the accused may be later acquitted) and to permit the unhampered preparation of the defense, at the same time minimizing the risk that the accused will not appear for his trial. Theoretically, the amount of bail should be set in the light of all the factors which bear upon the risk of the accused's nonappearance for trial: the seriousness of the offense, the strength of the evidence, the accused's character, history, reputation, roots in the community and his financial ability to secure bail. In practice, the magistrate who fixes the amount of bail seldom has the benefit of the comprehensive study which would reveal all these matters; thus bail is generally set solely according to the nature of the offense charged.

Bail after conviction pending appeal is generally held not to be a constitutional right. The reasons for bail after conviction are naturally weaker than for bail before conviction. Nevertheless, most U.S. jurisdictions allow bail after trial pending appeal unless the appeal is frivolous.

In the United States the sureties on bail undertakings are generally surety companies and professional bondsmen who charge fees for their services, rather than (as in England) the accused's friends and relations. Much of the criticism concerning bail in the U.S. has been directed at unscrupulous bondsmen for their excessive fees and financial irresponsibility; at the professional bondsman who, in practice, exercises little supervision over the accused; at the lack of financial deterrent upon the accused to abscond, since the surety, not the accused, is expected to pay upon default; and at the fact that the indigent accused, who may deserve pretrial freedom, cannot secure it, whereas the professional criminal finds it relatively easy to do so. A few jurisdictions have made it a separate criminal offense to "jump bail" instead of appearing as required, thus creating a personal deterrent to absconding. (A. W. St.)

England.—In England bail is obligatory in all summary cases. Bail may be granted in all cases other than treason, but it is not usually granted in cases of murder or attempted murder. The granting of bail to accomplices has been held to be improper because of the danger of their absconding. The sureties must be sufficient in the opinion of the court to answer for the sum which they are bound, and, as a rule, only householders are accepted; an accomplice of the person to be bailed or an infant would not be accepted. In cases of treason, bail can be granted only by a secretary of state or by the queen's bench division. The power of admitting a prisoner to bail is judicial and not ministerial, and the exercise of the discretion must not be punitive, the chief consideration being the likelihood of the prisoner's failing to appear at the trial. This must be gauged from the nature of, and the

evidence in support of, the accusation, the position of the accused and the severity of the punishment which his conviction will entail, as well as from the independence of the sureties. The Bail act of 1898 gives a magistrate power, where a person is charged with felony or certain misdemeanours, or where he is committed for trial for any indictable offense, to dispense with sureties if in the magistrate's opinion this dispensation will not tend to defeat the ends of justice.

A surety may be examined on oath as to his means, while the court may also require notice to be given to the plaintiff, prosecutor or police. A person who has been taken into custody without a warrant, for an offense not apparently of a serious nature, and who cannot be brought before a court of summary jurisdiction within 24 hours, may be admitted to bail by a police officer of superior rank or by the officer in charge of the police station; and this can be done while inquiries are being made (Criminal Justice acts, 1914 and 1925).

Where magistrates have refused bail, application may be made to the queen's division, and the court of trial has power to grant bail when necessary. Bail may be granted to a convicted person who has been granted leave to appeal, and this power has been enlarged in certain respects by s. 37 of the Criminal Justice act, 1948. *See* also ARREST. (W. DE B. H.; W. T. Ws.)

BAILEY, GAMALIEL (1807–1859), U.S. abolitionist, was the editor of *The National Era*, the first U.S. abolitionist journal (1847–1860). Born at Mount Holly, N.J., on Dec. 3, 1807, he graduated from the Jefferson Medical college in Philadelphia in 1827. In 1834 he was a lecturer on physiology at the Lane Theological seminary, Cincinnati, O., when the Lane seminary debates on slavery occurred. These stirred him to become an ardent abolitionist. In 1836 he joined James G. Birney in editing the *Cincinnati Philanthropist*, the first antislavery organ in the west and, soon becoming sole proprietor, continued it despite his printing office being wrecked three times and the entire building being destroyed by proslavery mobs. In 1843 he launched a daily paper, the *Herald*.

In Jan. 1847 Bailey became editor of *The National Era*, established in Washington, D.C., by the American and Foreign Anti-Slavery society. This paper had a considerable circulation and exerted a strong political and moral influence. Nathaniel Hawthorne, John Greenleaf Whittier and Theodore Parker were contributors, and in it Harriet Beecher Stowe's *Uncle Tom's Cabin* first appeared as a serial in 1851–52. In 1853 Bailey's health began to decline, and on June 5, 1859, while on a voyage to Europe for his health, he died.

BAILEY, LIBERTY HYDE (1858–1954), U.S. botanist, horticulturist and educator, who pioneered in transforming American horticulture from a craft to an applied science, was born at South Haven, Mich., on March 15, 1858. He graduated from Michigan Agricultural college in 1882 and served as an assistant to Asa Gray at Harvard university and as professor of horticulture at Michigan State college (1884–88). At Cornell university, Ithaca, N.Y., he became professor of horticulture in 1888. As dean of the New York State College of Agriculture at Cornell (1903–13), chairman of Theodore Roosevelt's Commission of Country Life (1907–08) and editor successively of three periodicals, Bailey provided national leadership in developing agricultural education and in improving farm living. As botanist he was an authority on the classification of the genera *Carex*, *Rubus*, *Brassica* and tropical American members of the palm family. In addition he founded (1920), and was director (1935–51) of, the world's first botanical institution devoted to studies on the classification and identification of cultivated plants, the Bailey hortorium, later a division of the New York State College of Agriculture at Cornell. He also was author of 63 books and editor of 4 encyclopaedic works in the fields of botany, horticulture and agriculture. He died in Ithaca on Dec. 25, 1954.

Bailey was a man of driving energy. As a diversion from administrative burdens and research in science he wrote two volumes of poetry and nine in the fields of rural sociology, religion and philosophy.

BIBLIOGRAPHY.—A. D. Rodgers III, *Liberty Hyde Bailey* (1949); G. H. M. Lawrence, "Liberty Hyde Bailey (1858–1954): An Appreciation," in *Baileya*, vol. iii, pp. 26–40 (1954), includes bibliography; P. Dorf, *Liberty Hyde Bailey* (1956). (G. H. M. L.)

BAILEY, PHILIP JAMES (1816–1902), English poet, was leader of the "spasmodic" school of poets, which included also S. J. Dobell and Alexander Smith. It was so named by W. E. Aytoun who parodied its style. Bailey was born in Nottingham, April 22, 1816, and educated at Glasgow university. He became a barrister of Lincoln's Inn, but in 1836 retired to write *Festus*, a version of the Faust legend which despite the typical "spasmodic" faults of turgidity and plagiarism, had, as Tennyson said, "very grand things in it." It appeared in 1839 and made a great impression. Its 50 scenes of blank verse dialogue, 20,000 lines in the first edition, were swelled by additions from Bailey's other and less successful works to 40,000 lines in the 11th edition of 1889. Typical of its mid-Victorian sentiment and style are the lines, "We live in deeds, not years . . . we should count time by heart-throbs." Bailey's other works included *The Angel World* (1850), *The Mystic* (1855) and *The Universal Hymn* (1867). He died at Nottingham, Sept. 6, 1902.

BAILEY, SAMUEL (1791–1870), English economist and philosopher whose chief contribution to economic analysis was his argument that value is a relationship and that it implies a state of mind, was born at Sheffield. He founded the Sheffield Banking company (of which he eventually became chairman) in 1831 and unsuccessfully sought to enter the house of commons in 1832 and in 1834.

His published works, which range over a wide field, include pamphlets on parliamentary reform, on the right of primogeniture and on currency restrictions, the most important of which are: *Essay on the Formation and Publication of Opinions* (1821), in which he argued that an individual's opinions are independent of his will; its sequel, *Essays on the Pursuit of Truth and on the Progress of Knowledge* (1829); *A Critical Dissertation on the Nature, Measures and Causes of Value* (1825; new ed., 1931), a criticism of the Ricardian school of political economy; *Review of Berkeley's Theory of Vision* (1842); and *Letters on the Philosophy of the Human Mind*, 3 vol. (1855–63).

In Bailey's economic theories may be traced germs of a subjective theory of value. He also emphasized the influence of monopoly in value formation; and his discussion of the various degrees of skill accruing to labour foreshadowed the rent-of-ability concept. He denied the reciprocal relationship between wages and profits, stressed the productivity of labour and sought to eliminate the pessimistic implications of David Ricardo's doctrines. His philosophical writings bore witness to his lively and critical intelligence but suffered from a limited knowledge of other schools. In politics he was a utilitarian radical opposed to state interference. He died on Jan. 18, 1870. (I. C. B.)

BAILIFF AND BAILIE. A bailiff is usually a minor court official with police authority to protect the court and with the power to serve and execute legal process. In earlier times it was a title of more dignity and power. The vestiges of the earlier meaning may be found in the use of the word in England to mean the chief magistrate of a village and in Scotland to denote an official appointed to exercise a local delegated jurisdiction, civil or criminal ("bailie"). In France, the word *bailli* once had the same meaning as seneschal, the primary representative of the feudal lord, who often exercised judicial functions. *See* JUDICIARY AND COURT OFFICERS. (P. B. K.)

BAILLIE, LADY GRIZEL (1665–1746), Scottish poet known for her songs "And werena my heart licht I wad dee" and "The ewe-buchtin's bonnie," was born at Redbraes castle, Berwickshire, on Dec. 25, 1665, the eldest daughter of Sir Patrick Hume (or Home), later earl of Marchmont. At the age of 12 she carried letters from her father to the imprisoned Scottish conspirator, Robert Baillie of Jerviswood (*q.v.*). During Baillie's trial, Sir Patrick spoke in his defense and was therefore himself regarded with suspicion. Redbraes castle was occupied by the king's troops and he was forced to hide in Polwarth church, where Lady Grizel brought him food. After Baillie's execution (1684) the family fled to Holland, where they remained until they could

return to Scotland at the revolution. In 1692 Lady Grizel married George Baillie, Robert Baillie's son. She died on Dec. 6, 1746.

Although Lady Grizel is known to have written several songs, only two are extant: "The ewe-buchtin's bonnie," which may have been inspired by her father's hiding in Polwarth church, and the well-known "And werena my heart licht I wad dee," which first appeared in *Orpheus Caledonius* (1725) and which was included in Allan Ramsay's *The Tea Table Miscellany* (4 vol., 1724–37).

See Lady Grizel Murray's (her daughter) *Memoirs . . . of the Right Honourable George Baillie of Jerviswood, and of Lady Grisell Baillie* (1822); R. S. Moncrieff (ed.), *The Household Book of Lady Grisell Baillie, 1692–1733,* Scottish Historical Society (1911).

BAILLIE, JOANNA (1762–1851), Scottish poet and dramatist who was a friend of Sir Walter Scott, was born at Bothwell, Lanarkshire, on Sept. 11, 1762. She was the younger sister of Matthew Baillie (*q.v.*). In 1784 she left Scotland with her mother, a sister of William and John Hunter, and her sister Agnes. Later the two sisters settled at Hampstead, where they passed the remainder of their lives. In 1790 Joanna Baillie published anonymously her *Fugitive Verses* and in 1798 the first volume of her *Plays on the Passions.* These, the title page explains, "attempted to delineate the stronger passions of the mind, each passion being the subject of a tragedy and a comedy." The second and third volumes were published in 1802 and 1812. At this period Joanna Baillie met Sir Walter Scott who wrote a prologue for the production of her play, *The Family Legend,* at Edinburgh in 1810 and of whom she became a lifelong friend. Earlier, in 1800, John Kemble and Sara Siddons acted in her play *De Montfort* at Drury Lane. At a later production of this play the leading part was taken by Edmund Kean. In 1804 her *Miscellaneous Plays* appeared. A complete edition of her dramatic and poetical works was published in 1851. She also wrote songs, some of which are adaptations of dialect folk songs. She died at Hampstead on Feb. 23, 1851.

BIBLIOGRAPHY.—*Dramatic and Poetical Works of Joanna Baillie* (1851); M. S. Carhart, *The Life and Work of Joanna Baillie* (1923). *See* also for Joanna Baillie's songs, C. Rogers, *The Modern Scottish Minstrel,* vol. i (1855).

BAILLIE, MATTHEW (1761–1823), Scottish pathologist whose *Morbid Anatomy,* published in 1793, was the first publication in English on pathology as a separate subject, was born at Shotts, Lanarkshire, on Oct. 27, 1761. He was educated at Balliol college, Oxford, and settled in London, where he practised medicine and taught anatomy. He was a nephew of William and John Hunter, the great anatomists, and a brother of poetess Joanna Baillie (*q.v.*). He died at Duntisborne, Gloucestershire, on Sept. 23, 1823.

See MEDICINE AND SURGERY, HISTORY OF: *Medicine in the 18th Century.*

BAILLIE, ROBERT (1599–1662), Presbyterian minister who represented Scotland at the Westminster assembly (1643) and was noted for his learning and moderation, was born in Glasgow. As minister of Irvine he refused to support the introduction of Laud's prayer book in Scotland (1637), though he was a moderate member of the Glasgow assembly (1638) at which the Church of Scotland broke away from the English episcopal system. He became professor of divinity at Glasgow (1642), and in 1661 was made principal of the university. He died in July 1662 in Glasgow. His *Letters and Journals,* edited by D. Laing (1841–42), are of great historical interest.

BAILLIE, ROBERT (BAILLIE OF JERVISWOOD) (*c.* 1634–1684), Scottish landowner and conspirator, was from 1676 associated with political and ecclesiastical disaffection in Scotland. Despairing of prospects there, he associated himself in 1683 with plans for a settlement in South Carolina which brought him into communication, in London, with the duke of Monmouth, Lord William Russell and their faction. Although, after the discovery of the Rye House plot (1683), he denied knowledge of or complicity in the plot, he admitted that an insurrection in Scotland was discussed. After six months' imprisonment in London he was sent back to Edinburgh, where the privy council fined him £6,000 for treason; then, by an irregularity which startled his contemporaries, he was indicted before the court of justiciary on the same charge, found guilty, and hanged on Dec. 24, 1684. (GN. D.)

BAILLOU, GUILLAUME DE (BALLONIUS) (1538–1616), French physician, studied and taught medicine in Paris. He has a place in the history of epidemiology because of two books posthumously published (1640) on epidemics, in which he revived the Hippocratic doctrine of "epidemic constitutions" which seems to have influenced the work of Thomas Sydenham (*q.v.*). Baillou first described whooping cough (1578), and he differentiated between rheumatism and gout, as Hippocrates had done.

His works include *Definitionum medicinalium liber* (1639), a glossary of Hippocratic terms; *Consilia* (1635–49); treatises on gynecology (1643) and gout (1643); and two books on epidemics and diseases (1640).

See MEDICINE AND SURGERY, HISTORY OF: *Early Greek and Roman Medicine.*

BAILLY, JEAN SYLVAIN (1736–1793), French astronomer and politician, born at Paris on Sept. 15, 1736, calculated an orbit for the comet of 1759 (Halley's), reduced N. de Lacaille's observations of 515 zodiacal stars, and was, in 1763, elected a member of the Academy of Sciences. His *Essai sur la théorie des satellites de Jupiter* (1766), was followed by *Sur les inégalités de la lumière des satellites de Jupiter* (1771) and by a series of important works on the history of science.

The Revolution interrupted his studies. Elected deputy from Paris to the states-general, he was chosen president of the Third Estate (May 5, 1789), led the famous proceedings in the Tennis Court (June 20), and acted as mayor of Paris (July 15, 1789, to Nov. 16, 1791). The dispersal by the national guard, under his orders, of the riotous assembly in the Champ de Mars (July 17, 1791), rendered him obnoxious to the infuriated populace, and he retired to Nantes, where he composed his *Mémoires d'un témoin de la Révolution* (published by Berville and Barrière, 1821–22), an incomplete narrative of the extraordinary events of his public life. Late in 1793, Bailly quitted Nantes to join his friend Pierre Simon Laplace at Melun; but was there recognized, arrested and brought (Nov. 10) before the revolutionary tribunal at Paris. On Nov. 12 he was guillotined.

See H. B. Sawyer-Hogg, *J. R. Astr. Soc. Can.,* vol. 48 (1949).

BAILMENT, a delivery of specific goods by one person, called the bailor, to another person, called the bailee, for some temporary purpose such as storage; transportation; deposit for sale; loan for use, with or without compensation; pawn or pledge; or repair. The Anglo-American law formerly divided bailments into three classes: (1) for the benefit of the bailor; (2) for the benefit of the bailee; and (3) for the benefit of both parties. In the first instance the bailee was said to owe only a duty of slight care to preserve the property concerned; in the second he owed a duty of great care; in the last he owed a duty of ordinary care. Correspondingly, if the chattel was lost or damaged he was liable in the first situation only for gross negligence, in the second for even slight negligence and in the third for ordinary negligence.

Logical difficulties involved in ascertaining and applying three degrees of care and negligence have caused juristic thinkers to generalize that the bailee owes such duty of care as becomes the reasonably prudent man "under the circumstances." The purpose and advantage anticipated from the bailment are considered as "circumstances" governing the extent of care owed by the bailee.

The bailee is usually not permitted to deny the right of the bailor to direct the disposition of the chattel when the purpose of the bailment has been completed unless he has been required to deliver it to one having a right to possession superior to that of the bailor. However, the burden of proof is upon the bailee to establish the better right of this third party.

Common types of bailments have been similar under most systems of law, and they were designated by specific names in the Roman law. Some of them have characteristic legal consequences; *e.g.*, the bailee for repairs has a lien which entitles him to retain possession until he has been paid for his service, as does the bailee for transportation.

See also AFFREIGHTMENT; FACTOR; LIEN; PAWNBROKING; PERSONAL PROPERTY; PUBLIC UTILITIES. (C. M. U.)

BAILY, FRANCIS (1774–1844), English astronomer who detected the phenomenon known as "Baily's beads," was born at Newbury, Berkshire, on April 28, 1774. He made a fortune on the stock exchange, and acquired a great reputation for his actuarial calculations. He retired from business in 1825. He had already, in 1820, taken a leading part in the foundation of the Royal Astronomical society; and its gold medal was awarded him in 1827, for his preparation of the Astronomical society's catalogue of 2881 stars. The reform of the *Nautical Almanac* in 1829 was set on foot by his protests; he recommended to the British association in 1837, and in great part executed, the reduction of Joseph de Lalande's and Nicolas de Lacaille's catalogues containing about 57,000 stars; he superintended the compilation of the British association's catalogue of 8,377 stars (published 1845); and revised the catalogues of Tobias Mayer, Ptolemy, Ulug-Beg, Tycho Brahe, Edmund Halley and Hevelius.

His notice of "Baily's beads," during an annular eclipse of the sun on May 15, 1836, at Inch Bonney in Roxburghshire, started the modern series of eclipse expeditions. The phenomenon, which depends upon the inequalities of the moon's limb, was so vividly described by him as to attract an unprecedented amount of attention to the totality of July 8, 1842, observed by Baily himself at Pavia. He completed and discussed H. Foster's pendulum-experiments, deducing from them an ellipticity for the earth of $\frac{1}{289}$; corrected for the length of the seconds-pendulum by introducing a neglected element of reduction; and was entrusted, in 1843, with the reconstruction of the standards of length. His laborious operations for determining the mean density of the earth, carried on by Henry Cavendish's method (1838–42), yielded for it the authoritative value of 5.66. Baily's *Account of the Rev. John Flamsteed* (1835) is of fundamental importance to the scientific history of that time. It included a republication of the British catalogue. Baily died in London on Aug. 30, 1844.

See J. Herschel, *Mon. Not. R. Astr. Soc.*, xiv (1844).

BAILY'S BEADS, a phenomenon seen during a total eclipse of the sun. Just before the moon's disk completely covers the sun the narrow crescent of sunlight is broken in several places, giving an appearance roughly compared to a string of beads. This is due to irregularity (mountains and valleys) on the edge of the moon's disk. These "beads" were named after Francis Baily (*q.v.*).

BAIN, ALEXANDER (1818–1903), British philosopher, chiefly distinguished for his work on psychology but influential also in the improvement of education in Scotland, was born at Aberdeen on June 11, 1818. The son of a weaver, he worked for some years at his father's trade but studied diligently in the evenings and, in 1836, won a bursary at Marischal college, Aberdeen. Graduating in 1840, he began to contribute to the *Westminster Review*, thus coming into contact with John Stuart Mill and his circle in London, who soon became his close friends. After some unsuccessful attempts to find a permanent appointment in Scotland, Bain accepted Edwin Chadwick's offer of a post under the board of health in London (1848–50). After this he held various other posts in London (in education or the civil service) for the next ten years. Two important publications of his in this period were *The Senses and the Intellect* (1855; 4th ed., 1894) and *The Emotions and the Will* (1859; 4th ed., 1899).

In 1860 Bain was appointed to the new chair of logic and English at Aberdeen. At this post he conscientiously set himself to promoting the reform of teaching methods in Scotland, with particular regard to his own two subjects. A series of books on English grammar and rhetoric (1863, 1866, 1872, 1874) was accompanied by a two-volume work on *Logic* (1870), notable for its detailed account of the application of logic to the natural sciences. His *Education as a Science* appeared in 1879.

Bain's practical services to education, which were recognized by the award of a doctorate of laws from Edinburgh university as early as 1869, did not preclude his pursuing his interest in psychological theory, which he further expounded in *On the Study of Character* (1861), *Mental and Moral Science: a Compendium of Psychology and Ethics* (1868) and *Mind and Body: the Theory of Their Relation* (1873; 5th ed. 1876). Moreover, it was he who founded the philosophical periodical *Mind*, which first appeared in 1876, with his pupil George Croom Robertson as editor.

Bain resigned his professorship in 1880, but was twice subsequently elected rector of his university (1881 and 1884). His later books included *James Mill: a Biography* (1882), *John Stuart Mill: a Criticism, With Personal Recollections* (1882), *Practical Essays* (1884), *On Teaching English* (1887), *Dissertations on Leading Philosophical Topics* (1903) and the posthumous *Autobiography*, edited by W. L. Davidson (1904). Bain died in Aberdeen on Sept. 18, 1903.

In ethics Bain followed John Stuart Mill's utilitarianism, but in logic he modified Mill's doctrine in some respects. To association psychology (*see* PSYCHOLOGY, HISTORY OF; and ASSOCIATION, MENTAL) he made important contributions. Adopting a rigorously scientific attitude to problems that earlier British philosophers had treated metaphysically, he presented mind not as a number of "faculties" but as a psychophysical unity and led the way in insisting on the need for investigation of those physical conditions (processes in the brain and in the nervous system) which play "a concurring part" in many mental states.

BAINBRIDGE, JOHN (1582–1643), English astronomer and physician, known for his work on comets, was born at Ashby-de-la-Zouch, Leicestershire. He started as a physician and practised for some years. Sir Henry Savile appointed him in 1619 to the Savilian chair of astronomy just founded by him at Oxford; Bainbridge was incorporated of Merton college and became in 1631 and 1635 respectively, junior and senior reader of T. Linacre's lectures. He wrote *An Astronomical Description of the late Comet* (1619); *Canicularia* (1648); and translated Proclus's *De Sphaera*, and Ptolemy's *De Planetarum Hypothesibus* (1620). Bainbridge died at Oxford on Nov. 3, 1643. Several manuscript works by him exist in the library of Trinity college, Dublin.

BAINBRIDGE, WILLIAM (1774–1833), U.S. naval officer, was born at Princeton, N.J., May 7, 1774. After considerable experience in merchant service he became an officer in the newly organized U.S. navy in 1798. He served in the war upon the Barbary states, being in command of the frigate "Philadelphia" when it was captured by the Tripolitans. He was a prisoner for a time, and upon his release returned to service in the merchant marine. At the outbreak of the second war with England in 1812 he was again commissioned in the U.S. navy, succeeding to the command of the frigate "Constitution." His notable victory in the South Atlantic was the capture of the British frigate "Java." After the close of the war and his retirement, he served as a member of the board of naval commissioners. He died July 27, 1833. (E. E. R.)

BAINVILLE, JACQUES (1879–1936), French political writer and historian, a member of the Académie Française from 1935 and a leading exponent of conservative ideals between World Wars I and II. Born at Vincennes, on Feb. 9, 1879, of a republican family, he early embraced the royalist cause under the influence of Maurice Barrès and Charles Maurras. He was closely associated with the royalist papers, *Gazette de France* and *Action française*. After a visit to Germany, he published a work on Bismarck (1907), emphasizing the German statesman's support of French republicanism.

His *Histoire de deux peuples* (1915, rev. 1933) dealt with the recurrent German invasions of France. His *Conséquences politiques de la paix* (1920), a reply to J. M. Keynes' *The Economic Consequences of the Peace*, attacked the treaty of Versailles and forecast the German menace. His *Histoire de France* (1924; Eng. trans. 1926) was later republished with other studies under the title *Heur et Malheur des Français*. His studies of German history were collected as *L'Allemagne romantique et réaliste*. Other historical studies, illustrating both his traditional outlook and his psychological insight, dealt with Napoleon and the mentality of dictators. His political philosophy, which found growing support toward the end of his life, opposed both plutocracy and democracy. In *Histoire de la III^e République* (1935; Eng. trans., *The French*

Republic, 1936) he predicted a German attack and a national revolution. He published a study of English political history, *L'Angleterre et l'Empire britannique* (1938). His essays, tales and prefaces were collected in *Jaco et Lori* (1927) and *Le Jardin des lettres* (1929). He died in Paris, Feb. 9, 1936.

BIBLIOGRAPHY.—*Collection bainvillienne*, ed. by J. Marcel, J. and R. Wittmann (1937 *et seq.*). *See* also H. Massis, *Le Souvenir de J. Bainville* (1936); C. Maurras, *J. Bainville et Paul Bourget* (1937); L. de Gérin-Ricard, *L'Histoire de France de Jacques Bainville* (1939).

BAIRAM, an Osmanli-Turkish word meaning "festival," applied in Turkish to the two canonical festivals of Islam. The first of these according to the calendar is the Lesser Bairam, in Arabic *'id al-fitr* ("Festival of Breaking Fast"), which follows immediately the fasting month Ramadan, occupying the first three days of the tenth month, Shawwal. Official receptions are held on it, and private visits paid; friends congratulate one another, and presents are given; new clothes are put on, and the graves of relatives are visited.

The second, Sacrifice Bairam, in Arabic *'id al-adha,* falls on the tenth, and three following days, of the last month of the year. Throughout the Muslim world, all who can afford it sacrifice at this time a legal animal, and either consume the flesh themselves or give it to the poor, commemorating the ransom of Ishmael with a ram. *See* also FEAST AND FESTIVAL.

See articles "Bairam," "'Id," "'Id al-Adha," and "'Id al-Fitr" in *Shorter Encyclopaedia of Islam* (1953).

BAIRD, JOHN LOGIE (1888–1946), British inventor and television pioneer, born on Aug. 13, 1888, at Helensburgh, Scot., was educated at Larchfield academy, the Royal Technical college and Glasgow university. He was the first to achieve television over any distance, he reproduced objects in outline (1924); transmitted recognizable human faces (1925); and in 1926, at the Royal institution, London, demonstrated the first true television. He produced the "noctovisor" for seeing in the dark (1927); he televised images from England to the "Berengaria" in mid-Atlantic (1928). In 1929 the German post office gave him facilities to develop a television service based on his system and two months later the British Broadcasting corporation lent its transmitter for him to continue his experiments. When the B.B.C. television service began in 1936 his system was in competition with another promoted by Marconi Electrical and Musical Instruments. Both continued side by side for some months, but in Feb. 1937 the B.B.C. adopted the Marconi E.M.I. system exclusively. Baird demonstrated television in natural colours (1939) and in 1946 was reported to have completed his researches on stereoscopic television. He died at Bexhill-on-Sea, Eng., on June 14, 1946.

(D. McK.)

BAIRD, SPENCER FULLERTON (1823–1887), U.S. naturalist, in his time the best informed man on the vertebrate fauna of North America, was born at Reading, Pa., Feb. 3, 1823. In 1838 a meeting with John J. Audubon, who gave Baird part of his own collection of birds, turned the young man's interest to ornithology. A year after his graduation from Dickinson college, Carlisle, Pa. (1840), he made an ornithological excursion through the mountains of Pennsylvania. After studying medicine for a time, Baird became professor of natural history in Dickinson college (1845).

From the time he began his studies in natural science, Baird saw the pressing need for raw materials. By the time he was 27 he had accumulated 3,500 skins of birds and collections of reptiles, embryos, skeletons and skulls of North American vertebrates. This became the nucleus of the vast collection of North American fauna which he assembled after he became assistant secretary of the Smithsonian institution in 1850. The great labour of correspondence, examination, description and editing of reports for the Smithsonian collection was accomplished by Baird, in connection with the publication of the 13 volumes of reports. In addition, Baird worked nights on the preparation of the volumes on birds, mammals and reptiles. His great monographs at once became classics of systematic zoology. With the appearance of his volume on birds began what Elliott Coues (*Popular Science Monthly*, vol. xxxiii, p. 553) calls the Bairdian period of American ornithology, lasting nearly 30 years. This volume, says Coues, "marked an epoch in the history of American ornithology."

In 1878 Baird succeeded Joseph Henry as secretary of the Smithsonian institution. Through Baird's efforts, congress created the commission of fish and fisheries in 1874 and placed Baird at its head, in which position he did work worth millions of dollars to the country and organized fish culture in the United States so well that it has been widely copied as a model by other countries.

Baird died at Woods Hole, Mass., Aug. 19, 1887.

His important works were: *Birds* (1858); *Mammals of North America* (1859); *History of North American Birds* (1875–84).

BAIRNSDALE, a town of Victoria, Austr., about 170 mi. E. of Melbourne by road or rail, lies on the Mitchell river near the head of Lake King (a lagoon). Pop. (1961) 7,427. It developed originally as a port for the shipment of produce from eastern Gippsland and the Monaro plains, but shipping services have been replaced by road and rail transport. Nearby are the resort areas of Gippsland lakes, Lakes Entrance and Ninety Mile beach.

Bairnsdale shire (area 948 sq.mi.) is chiefly pastoral and agricultural, with dairying, sheep and cattle grazing, fruit and corn growing, timber and freestone quarrying. There are tanneries and sawmills, and butter, soap and cordials are produced.

BAIUS (BAJUS), **MICHAEL** (MICHAEL DE BAY) (1513–1589), Flemish theologian, whose work powerfully influenced that of Cornelius Jansen (*q.v.*), was born at Melin in Hainaut. Educated at Louvain, he studied philosophy and theology and held various university appointments there. About 1550, with John Hessels, he began to advance revolutionary doctrines of grace and justification, founded on a new interpretation of St. Augustine. Baius' numerous short treatises on theological subjects incurred censures by ecclesiastical authorities; in 1567 Pius V condemned 79 propositions in the bull *Ex omnibus afflictionibus.* Baius submitted, but indiscreet utterances by himself and his supporters led to a new condemnation in 1579 by Gregory XIII. Baius, however, kept his professorship, and became chancellor of Louvain in 1575; he died there on Sept. 16, 1589. The most distinctive features of "Baianism," which are found also in some Protestant writers, concern the fall of man. Baius held that the innocence of Adam and Eve was part of their nature, so that the first sin destroyed intrinsic principles of human nature.

His principal works were published in collected form in 1696. *See* F. X. Jansen, *Baius et le Baianisme* (1927). (N. J A.)

BAIXO ALENTEJO, a province of southern Portugal formed in 1936 from parts of old Alentejo and Estremadura (*qq.v.*) provinces, includes the district of Beja and part of Setúbal (*qq.v.*). Pop. (1950) 375,147; area 5,322 sq.mi. Most of the province is composed of a vast, rolling plain 450–600 ft. above sea level, forming the watershed between the Guadiana and Sado. It is characterized by large estates, nucleated settlements at infrequent intervals and extensive sericulture. The richest lands centre on Beja, with extensive cork oak forests on the west and evergreen oak woodlands east of the Guadiana in Além-Guadiana. The pasturage of the Cotenda de Moura, formerly communal to both Spanish and Portuguese shepherds, was eventually divided in 1893. The lower Sado valley has one of the most important irrigation and settlement schemes of Portugal. Beja (pop. 1950, 14,028) is the capital and chief agricultural centre but other towns are small and widely scattered; *e.g.*, Serpa (7,193), Aljustrel (5,783), Mértola (6,368) and Cuba (4,387).

(J. M. Ho.)

BAJA, a town of south Hungary, lies a little to the east of the Danube main stream on the low, sandy terrace above the flood plain of the river. Pop. (1960) 30,355. It has an established importance as a rail and road intersection point, since the Danube a few miles away is crossed by a rail bridge. Before the partition of the Austro-Hungarian empire it was the main export centre of the Bačka farming region (now part of Yugoslavia). Baja trades in corn, cattle and wine, and has some manufacture associated with farming and some textile industries. The traditional German and Jewish groups in the town disappeared after World War II.

(H. G. S.)

BAJA CALIFORNIA: *see* CALIFORNIA, LOWER.

BAJA VERAPAZ, a department in central Guatemala. Area 1,206 sq.mi.; pop. (1964) 95,663. Its capital is Salamá. This department is located in the structural valley drained by the Polochic river, there called the Panimá, and extends over the intervening ridge to the Motagua valley. Its few inhabitants raise maize, beans, coffee, sugar cane and fruit. It is reached by road to Cobán, or down the Polochic river. A proposed road would give it access directly southward to Guatemala City. (P. E. J.)

BAJAZET: *see* BAYAZID I and BAYAZID II.

BAJER, FREDRIK (1837–1922), Danish author and politician, was born in Vester Egede in Zealand on April 21, 1837. He entered the army, but was discharged when it was reduced after the 1864 war with Prussia. He then started working for the emancipation of women, Scandinavian co-operation and the peace movement. He was a founder of the Danish Women's association in 1871 and established in 1882 the Association for the Neutralization of Denmark (named in 1885 the Danish Peace association and after World War II the Danish United Nations' association or the Danish Peace association).

As a left-wing liberal member of the Danish parliament 1872–95 he was an advocate of international arbitration treaties and had a considerable influence on the development of the Danish policy of neutrality. He took the initiative in the first Scandinavian peace conference in 1885 and in the formation of the International Peace bureau in Bern, Switz., in 1891; he was president of the bureau until 1907. He also actively supported Danish participation in interparliamentarian conferences. The Nobel peace prize was conferred on him in 1908.

Bajer died in Copenhagen Jan. 22, 1922.

See *Fredrik Bajers Livserindringer udgivne af hans Sön* (1909). (H. LN.)

BAKELITE, a synthetic resin developed in 1909 by L. H. Baekeland in the U.S. It has many industrial applications, chiefly as an electrical insulator. It is prepared by the chemical interaction of phenolic substances, such as phenol and cresol found in coal tar, and aldehydes such as formaldehyde, a derivative of methyl alcohol obtained either synthetically or by the distillation of wood.

BAKER, AUGUSTINE (baptismal name DAVID) (1575–1641), monk of the English Benedictine congregation, important writer on ascetic and mystical theology, was born at Abergavenny, Eng., on Dec. 9, 1575, and died in London on Aug. 9, 1641. On the basis of his personal experience and much reading, Baker, a convert to Roman Catholicism, evolved an ascetical doctrine that could lay no claim to originality but that was none the less vigorously attacked. There was nothing novel in his summarizing the ascetic life under the headings of mortification and prayer. The attack was in fact directed not so much against his teaching on the first of these as against that concerning the second, for he was explicit in relegating "method," which in the 15th and 16th centuries had come to be emphasized more and more, to a subordinate role. Even more serious in the opinion of some was his teaching on the subject of spiritual direction, for guidance came to the soul, he taught, from God himself and was to be sought and found in prayer. On this point, too, he may be said to represent a reaction against certain exaggerated tendencies of his time.

Baker's ascetic doctrine was committed to writing after his appointment in 1624 to the post of spiritual director of the English Benedictine nuns at Cambrai, France, and in his voluminous works, of which comparatively few have been published, he has in mind primarily what he calls "interior" souls. For this class of persons, dedicated to the contemplative life in the cloister, he finds "method" for the most part a hindrance rather than a help. He advises beginning with "affective" prayer. As a help to those who sought his counsel or were entrusted to his care, he recommended especially two English works of the 14th century: the anonymous *Cloud of Unknowing* and Walter Hilton's *Ladder of Perfection*. This recommendation is in full accord with his insistence on aspirations and acts of the will.

Several years after his death there was compiled from more than 40 treatises he had left in manuscript a systematic work entitled *Sancta Sophia*, which covers the entire range of ascetic and mystic theology (2 vol., 1657; reprinted in one volume, 1876; under the title *Holy Wisdom*, 1911; an abridgment, *Contemplative Prayer*, by Benedict Weld-Blundell, appeared in 1907, and the first volume of a projected three-volume re-edition of this same abridgment was published in 1927). Other of his writings available in print are *Secretum*, a commentary on the *Cloud of Unknowing*, of which the first section is a kind of spiritual autobiography, published by Justin McCann under the title *The Confessions of Venerable Fr. A. B.* (1922); the second section is an exposition of the *Cloud* itself, edited by McCann (1924 and later); and *The Inner Life and Writings of Dame Gertrude More*, 2 vol., published by Weld-Blundell (1910).

BIBLIOGRAPHY.—A register of his writings and a list of printed books deriving from him are included in *The Life of Fr. A. B.* by Peter Salvin and Serenus Cressy (two distinct biographies in one volume), ed. by J. McCann (1933); a catalogue of manuscripts is to be found in *Memorials of Fr. A. B. and Other Documents Relating to the English Benedictines*, ed. by McCann and Hugh Connolly (1933). *See* also Abbot Cuthbert Butler, *Downside Review*, 51:577–595 (1933); Norbert Sweeney, *Life and Spirit of Fr. B.* (1861); David Knowles, *The English Mystics* (1927); Ursmer Berlière, *L'Auteur de "Sancta Sophia," Dom A. B.* (1929; offprint from *Revue liturgique et monastique XIII–XIV*); *Dictionnaire de Spiritualité*, vol. i, 1205–06 (1937). (AM. S.)

BAKER, SIR BENJAMIN (1840–1907), English civil engineer responsible for designing the railway bridge over the Firth of Forth, Scot., was born at Keyford, Somerset, on March 31, 1840. At 16 he was apprenticed at the Neath Abbey ironworks and in 1862 became an assistant to the consulting engineer Sir John Fowler, whose partner he became in 1875. Baker was made responsible in 1869 for the construction of the London underground district railway from Westminster to the city and, with Fowler and later associates, was consulted on the building of the city and south London, Central London and Bakerloo tube railways, which were all bored deep in the London clay. He also undertook work on the docks at Avonmouth and at Hull, and arranged the transport by sea of Cleopatra's Needle from Egypt in a cylindrical vessel and its re-erection on the Thames embankment in London.

Among Baker's greatest works was the design of the Forth bridge, erected by W. Arrol, and on its completion Baker was knighted. He served on government commissions and boards, including that on storing the waters of the Nile for irrigation, and he was consulting engineer on the Aswan dam in Upper Egypt. In the United States he was consulted by James B. Eads on the construction of the St. Louis bridge over the Mississippi river and by the promoters of the first Hudson river tunnel. Baker was president of the Institution of Civil Engineers in 1895–96, contributed valuable papers to its *Proceedings*, and was a vice-president of the Royal society from 1896. He died at Pangbourne, Berkshire, on May 19, 1907.

See *Minutes of Proceedings of the Institution of Civil Engineers*, clxx, p. 377 (1907). (S. B. HN.)

BAKER, GEORGE FISHER (1840–1931), U.S. financier and philanthropist, was born in Troy, N.Y., March 27, 1840. When the national banking system was created in 1863, Baker joined with John Thompson and sons to establish the First National Bank of New York city. He started out as a teller and a small stockholder, and in 1865 was made cashier and active head of the bank. As a young man of 25, he was frequently consulted by the U.S. secretary of the treasury. In 1877 he became president of the bank and under his direction it became one of the strongest in the United States. By 1910 Baker ranked with J. P. Morgan and James Stillman as a force in American finance, and served as director of many corporations. His benefactions included large gifts to the Metropolitan Museum of Art and the American Red Cross. Among his largest gifts was $6,000,000 for the graduate school of business administration of Harvard university. He died May 2, 1931. (J. R. LT.)

BAKER, GEORGE PIERCE (1866–1935), teacher of some of the most notable United States dramatists, was born on April 4, 1866, at Providence, R.I. During his 36 years on the Harvard faculty (1888–1924), he lectured on dramatic history and theory and taught such playwrights as Eugene O'Neill, Phillip

Barry, Sidney Howard and Thomas Wolfe in his "47 Workshop" playwriting laboratory. Emphasizing practical construction and creative individuality, Baker fostered an imaginative realism observable in Barry's comedies and O'Neill's *Long Day's Journey Into Night*. From 1925 until he retired in 1933 Baker was professor of history and technique of drama at Yale, founding there the Yale drama school and directing the University theatre. Many critics relate the most modern techniques in theatre, motion-picture and television production to Baker's work at Yale. He was a pioneer in the Little Theatre movement and American Folk Dance society, and his annual illustrated lecture tours, following a 1907 Sorbonne lectureship, introduced many Americans to European ideas of theatre art. His Elizabethan productions employed the platform stage as early as 1891 and revolving and wagon stages after 1926. He also was first president of the National Theatre conference (1932) and long advocated an American National Theatre and Academy. Baker's belief in the unity of all the arts in the theatre produced the Harvard Theatre collection and stimulated the professional stature of university theatres. Of his writings, the best known are *The Development of Shakespeare as a Dramatist* (1907) and *Dramatic Technique* (1919). He died Jan. 6, 1935.

See W. P. Kinne, *George Pierce Baker and the American Theatre* (1954). (W. P. K.)

BAKER, HENRY (1698–1774), English naturalist and poet, was born in London on May 8, 1698. His invention of a system for instructing the deaf-mute brought him to the notice of Daniel Defoe, whose youngest daughter, Sophia, he married in 1729. A year before, under the name of Henry Stonecastle, he was associated with Defoe in starting the *Universal Spectator and Weekly Journal*. He contributed many memoirs to the *Transactions* of the Royal society, and in 1744 received the Copley gold medal for microscopic observations on the crystallization of saline particles. Baker was one of the founders of the Society of Arts, in 1754. He died in London on Nov. 25, 1774. His name is perpetuated by the Bakerian lecture of the Royal society, for the foundation of which he left by will the sum of £100. Baker's verse—of which several volumes, including translations from Latin and French, were published—was characterized by T. F. Henderson as "spirited and rhythmical, but the sentiments are hackneyed, and the wit artificial."

BAKER, NEWTON DIEHL (1871–1937), lawyer, political leader and U.S. secretary of war in World War I. He was born at Martinsburg, W.Va., Dec. 3, 1871, and was educated at Johns Hopkins university and at Washington and Lee university. In 1897 he began the practice of law in his home town, moving later to Cleveland, O. There he soon distinguished himself as an able lieutenant of Mayor Tom L. Johnson in the latter's long struggle for municipal reforms. He was appointed city solicitor by the mayor in 1902 and held that office by election from 1904 to 1912. Elected thereafter mayor of Cleveland, he served for two terms, 1912–16.

On the floor of the Democratic national convention of 1912 he fought successfully to have the votes of districts recognized as independent of the instructions of the state conventions, thereby contributing substantially toward the nomination of Woodrow Wilson. He declined Wilson's offer of the post of secretary of the interior in order to push forward his efforts on behalf of municipal reforms in Cleveland. Three years later, on March 7, 1916, Baker was appointed secretary of war. Although he was, as he himself said, so much of a pacifist that he "would fight for peace," he soon submitted to congress a plan for universal military conscription; and, backed by the president, he remained at the head of the war department throughout World War I and to the end of Wilson's term of office. In Jan. 1918, administration policies relating to the conduct of the war were severely criticized, in part, at least, on a partisan basis, by the senate committee on military affairs. Baker defended his record before the committee, and contended that never in history had an army of similar size been raised, equipped and trained so quickly. President Wilson thereafter issued a strong public statement in Baker's defense.

At the close of the Wilson administration Baker resumed the practice of law in Cleveland. In the Democratic convention in 1924 he made a strenuous but losing fight for a strong League of Nations plank. Four years later (1928) he was appointed by President Coolidge to the Permanent Court of Arbitration at The Hague; in 1929 President Hoover appointed him to membership on his Law Enforcement commission; and in 1936 he published a book entitled *Why We Went to War*. To the end of his life Baker maintained his concern with civic affairs and national welfare. He died in Cleveland, on Dec. 25, 1937. (K. E. Bd.)

BAKER, RAY STANNARD (pen name, DAVID GRAYSON) (1870–1946), U.S. author, was born in Lansing, Mich., April 17, 1870. He graduated from Michigan Agricultural college in 1889 and after further study in law and literature at the University of Michigan, turned his attention to writing, becoming a reporter for the *Chicago Record* in 1892. He soon began writing also for *Outlook*, *McClure's*, and other magazines. He left the *Record* in 1898 to become a free-lance writer and thereafter spent some years on the staff of *McClure's*. In 1906 he joined Lincoln Steffens, Ida M. Tarbell and others of the so-called muckraker group in establishing and editing the *American Magazine*. Meanwhile he had been experimenting with a different kind of writing, and in 1907 published *Adventures in Contentment*, the first of his books to appear under the pen name David Grayson. These homely essays, and others of the same nature which followed through the years, were widely read in many countries. In 1910 Baker moved his family to Amherst, Mass., which remained his base of operations to the end of his life, though he continued to range the world widely. At President Wilson's request he headed the American Press bureau at the Paris peace conference, 1919; and in later years he gained increasing recognition as an authority on Woodrow Wilson. Among his 18 books on the Wilson period was the 8-volume authorized Wilson biography (1927–39). Upon publication of the final volume of this series, covering the war years, Baker received the Pulitzer prize for biography. He died at Amherst, July 12, 1946.

The main body of the Ray Stannard Baker papers is in the manuscript division of the Library of Congress; a small group of his papers is in the library at Princeton university; and hundreds of warmhearted letters from people all over the world, addressed to David Grayson, are, with other books and memorabilia, in the Ray Stannard Baker memorial room at the Jones library, in Amherst, Mass. *See* also Baker's autobiographical volumes, *Native American* (1941); *Under My Elm* by David Grayson (1942); and *American Chronicle* (1945). (K. E. Bd.)

BAKER, SIR RICHARD (*c.* 1568–1645), English writer and author of the *Chronicle of the Kings of England*, was educated at Hart hall, Oxford, studied law in London and traveled abroad. A member of parliament in 1593 and 1597, he was living at Highgate, Middlesex, in 1603, when he was knighted, but later settled at Middle Aston, Oxfordshire, and was high sheriff of that county, 1620–21. He married soon afterward. Encumbered by the debts of his wife's family, the Mainwarings of Shropshire, Baker was reported a crown debtor in 1625 and his property seized. He was imprisoned in the Fleet prison about 1635 and remained there, devoting himself to literary work, until his death on Feb. 18, 1645.

His best-known work, which included translations from Cato (1636), *Meditations on the Lord's Prayer* (1637) and a series of meditations on the psalms (1639), was *Chronicle of the Kings of England* (1643). This, though of small historical value, was once popular and is often referred to by Addison and Steele. He also wrote *Theatrum Redivivum*, an answer to William Prynne's *Histriomatrix*, published posthumously in 1662. (Rd. C. G.)

BAKER, SIR SAMUEL WHITE (1821–1893), English explorer, shares with John Hanning Speke the distinction of having discovered the sources of the Nile. He was born in London on June 8, 1821, the son of a West India merchant. After an unconventional education, partly in Germany, he spent two years in Mauritius (1843–45), then eight in Ceylon (1846–55) where he founded an agricultural settlement which was later developed into a tea garden. He traveled in the near east from 1856 to 1860. In 1861 he went to Africa and, after a year spent exploring the Nile tributaries on the Sudan-Abyssinian border, sailed up the White

Nile to Gondokoro. There he met Speke and J. A. Grant who had come from Zanzibar via Lake Victoria and, guided by the information which they gave him, on March 14, 1864, he reached the lake which he named "Albert," and which proved to be part of the Nile system. Baker returned to England in Oct. 1865 and was knighted in the following year. In 1869, at the request of the khedive Ismail, he undertook the command of a military expedition to the equatorial regions of the Nile, with orders to put down the slave trade, and to annex new territory of which he was appointed governor-general for four years; his successor in this post was Col. Charles George Gordon. Returning to England in 1873, he settled at Sandford Orleigh in south Devon and died there on Dec. 30, 1893. Baker was an authority on firearms and a prolific writer. His chief books are *Rifle and Hound in Ceylon* (1853), *Eight Years' Wanderings in Ceylon* (1855), *Albert Nyanza* (1866), *The Nile Tributaries of Abyssinia* (1867), *Ismailia* (1874). He was twice married, first to Henrietta Martin who died in 1855, and in 1860 to Florence von Sass, an intrepid Hungarian lady who accompanied him on his African travels.

See T. Douglas Murray and A. Silva White, *Sir Samuel Baker* (1895); Dorothy Middleton, *Baker of the Nile* (1949). (D. MN.)

BAKER ISLAND, a coral atoll in the central Pacific ocean (lat. 0° 12′ N., long. 176° 29′ W.) with a land area of less than 1 sq.mi. Capt. Elisha Folger of Nantucket discovered it in 1818. It was rediscovered by Capt. Michael Baker of New Bedford in 1839, and his name replaced the earlier "Nantucket" or "New Nantucket." It was worked for guano by U.S. interests from 1857 to 1876 and by a British company between 1883 and 1890.

The U.S. government landed a "token" colony of Hawaiians there in 1935, and on May 13, 1936, Pres. Franklin D. Roosevelt placed it under the jurisdiction of the department of the interior. There were intermittent Japanese attacks beginning Dec. 8, 1941, and the four U.S. colonists were evacuated on Jan. 31, 1942. United States forces landed on Baker island Sept. 1, 1943, and built an airstrip which was an important staging point for air search and photo reconnaissance until Jan. 1, 1944. The civilian colony was not re-established after World War II. (J. H. K.)

BAKERSFIELD, a city of California, U.S., in the southern San Joaquin valley, 292 mi. S. of San Francisco and 113 mi. N. of Los Angeles; seat of Kern county. The town was founded along the Los Angeles and Stockton road in the mid-1860s by Thomas Baker, who reclaimed swamplands along the nearby Kern river. It was an agricultural trade centre for the mines of the Sierra Nevada and the Owens valley in the 1860s and 1870s. Bakersfield became the seat of government for Kern county in 1874, when the county seat was moved from Havilah, where it had been located since 1866. The Southern Pacific railroad reached the town in 1874, and the Santa Fe, in 1898. Both companies established shops at Bakersfield. Incorporated in 1873 and disincorporated in 1876, the town was reincorporated in 1898. San Francisco capitalists, acquiring large-scale landholdings, helped to develop a canal system to distribute the water of the Kern river. Upon the settlement of a water controversy in the 1880s, the region became important in the production of grain, alfalfa and livestock. The discovery of the Kern river oil fields in 1899 brought an extensive petroleum industry, which centred at Bakersfield. The town was quickly rebuilt after a fire destroyed the business section in 1889; and again after an earthquake brought widespread damage in 1952. Bakersfield grew steadily throughout the 20th century with increasing production of petroleum products, livestock raising and mechanized farming of potatoes, grapes, alfalfa and grain. The population was scarcely 5,000 in 1900; in 1960 it was 56,848. Pop. (1960) standard metropolitan statistical area (which comprises Kern county) 291,984. (For comparative population figures *see* table in CALIFORNIA: *Population.*)

Bakersfield is the home of Bakersfield college, a junior college, the Kern County Philharmonic orchestra, the Kern County Musical association, the Kern County museum, the Bakersfield Community theatre, the Kern County Free library and the Cunningham Art gallery. (W. H. Bo.)

BAKER STREET IRREGULARS, an informal society of lovers of the "Sherlock Holmes" stories by Sir Arthur Conan Doyle (*q.v.*). Named after the "detective police force" of that name appearing in the stories and composed of young boys ("street Arabs") employed by Holmes to ferret out obscure information in the London underworld, the society was founded in New York on June 5, 1934, with the writers Christopher Morley and Elmer Davis as the leading spirits. The B.S.I. meets once a year on Holmes's birthday, the first Friday after Jan. 1, and has a membership limited to 60 (the number of Sherlock Holmes stories). The first officers elected were Christopher Morley ("Gasogene-cum-Tantalus") and Edgar W. Smith ("Buttons-cum-Commissionaire"). The society publishes the *Baker Street Journal,* "An Irregular Quarterly of Sherlockiana" containing studies of the "Canon," and has over a dozen affiliated ("Scion") societies in the United States, besides others in England, Canada and Denmark. (D. MD.)

BAKEWELL, ROBERT (1725–1795), outstanding English pioneer in livestock breeding, was born in 1725 at Dishley, Leicestershire, and spent his life there. His experiments on the improvement of the breed of cattle and sheep were particularly successful. Previously the interest had been in getting sheep bearing large fleeces and cattle large and strong for work; Bakewell, however, bred for meat and was among the first to do so. Production was to be economical; the animals were to fatten quickly without making too much bone or offal. He chose the Leicestershire longhorns as his subject and had remarkable success with them as meat producers. They were not, however, good milkers and were eventually supplanted by the Durham shorthorns bred at Ketton by Charles Colling, who had studied Bakewell's methods. Bakewell's sheep, the Leicesters, were more permanently successful. He jealously guarded the secrets of his guiding principles, but his methods are known to have included selection, inbreeding—then an innovation—and culling. He refused to sell his sires though he would let them out by the season, and so famous did they become that in 1789 he received a total of 3,000 guineas in letting fees. He was equally successful with his general farm management and the irrigation of his meadows. Visitors came from home and abroad to see and to learn and were entertained lavishly in his bachelor establishment. He died on Oct. 1, 1795.

See H. Cecil Pawson, *Robert Bakewell* (1957). (E. J. R.)

BAKHCHISARAI, a town in the Crimean *oblast* of the Ukrainian Soviet Socialist Republic, U.S.S.R., lies along the narrow, winding valley of the Churuk-Su, on the Simferopol-Sevastopol railway. The population in 1959 was 10,852. Before passing to Russia in 1783 it was the capital of the Crimean khanate. The town is picturesque, with many buildings of historical and architectural interest, making it an important tourist centre. The palace of the Tatar khans built in 1519 by Abdul-Sahal-Girai, destroyed in 1736 and restored by G. A. Potemkin, is now the Suvorov museum. The vicinity is mountainous and east of Bakhchisarai is the deserted cliff city of Chufut-Kaleh, once the centre of the Karaite Jews. (R. A. F.)

BAKHTIARI, one of the great nomad tribes of Persia (Iran), occupying the plains and mountains between Shushtar and Isfahan (east-west) and from the Dezful river to Behbehan (north-south). This area of roughly 25,000 sq.mi. lies in the Bakhtiari-Chahar Mahall and Khuzistan regions. The Bakhtiari population was estimated at 400,000 in the 1960s, one-third being still nomadic. They speak the Luri dialect of Persian and are Shi'ah Muslims.

As pastoral tent dwellers, they depend on their flocks of sheep, goats and cattle; for the sake of these they migrate annually 150 mi. between winter pastures in the plains and summer pastures in the mountains. Agricultural products are obtained by trade, or as tax from dependent villages. The tribe consists of two patrilineal groups, Haft Lang and Chahar Lang, each subdivided into sections under hereditary chiefs. Until 1949 all were united under one paramount chief, the Ilkhan, with a deputy, the Ilbeg. These offices were elective from the chiefly families, subject to approval by the shah. Bakhtiari chiefs have long been influential in Persian politics. In 1905–06 they pressed for constitutional reform. The chief Sardar Asad, former minister of war, opposed Riza Shah's suppression of nomadism in the late 1920s. Unrest followed his

imprisonment and execution, and during World War II many settled tribesmen resumed nomadism. Subsequently, many Bakhtiari held prominent public office. *See* also LURISTAN; IRAN: *The People;* KHUZISTAN.

BAKI (MAHMUD ABDÜLBAKI) (1526–1600), the most representative Turkish poet of the classical era and recognized as the greatest gazel (lyric) writer in Turkish literature, was born in Istanbul in 1526, son of a muezzin. After a period of apprenticeship to a saddler, he studied law and, rising rapidly in his profession, mixed with men of letters and became accepted at the court of Suleiman the Magnificent. His gazels constantly expound a favourite theme of the divan poets—the ephemeral nature of this world's joys. The beauties of nature, youth, happiness, high estate are all doomed; love, drink and be merry while you may. Baki's mastery of form expresses itself in perfect versification, a meticulous choice of words and a skilful use of onomatopoeic effect by which he achieves great musicality. His masterpiece, the famous elegy on the death of Suleiman, combines grandeur of style with sincere feeling. He died in Istanbul on April 7, 1600.

BAKING: *see* BREAD; FOOD PREPARATION.

BAKST, LÉON NIKOLAEVICH (LEV SAMUILOVICH ROSENBERG) (1866–1924), Russian painter, who revolutionized the application of the decorative arts of the theatre, passed his childhood in St. Petersburg (Leningrad). He attended the Imperial Academy of Arts, but left after painting a too realistic "Pietà." A member of the Society of Painters in Water Colours and a teacher to the children of the grand duke Vladimir, he succeeded both as a court painter and in the fashionable world. From 1900 he was scenic artist, first at the Hermitage court theatre and afterward at the Imperial theatres. He designed the scenery and accessories for the tragedies of Sophocles in the spirit of the Greek theatre and in the archaic style of the Aegina sculptures. He made a voyage to Greece and Crete of which he wrote an account, and his famous picture "Terror Antiquus" expresses his vision of mythic Greece. In 1906 he exhibited in the Russian section of the Salon d'Automne in Paris. Two years afterward he achieved considerable fame as the chief painter of scenery for the Russian ballets produced by Diaghilev. "Cleopatra," "Scheherazade" (1909) and "Daphnis and Chloe" were among his most notable achievements. He returned to Russia and founded a liberal school of painting.

Afterward he settled in Paris, where he designed the setting of the tragedies of D'Annunzio and of a play of Émile Verhaeren. He painted the scenery and designed the costumes for the "Sleeping Princess," the fairy ballet of Tchaikovsky produced in London in 1921. He also produced several plays at the Paris Opéra, among them the "Bewitched Night." Bakst aimed at unity of impression. The influence of his genius may also be seen in the costumes of the time. He died in Paris on Dec. 24, 1924.

See André Levinson, *The Story of Léon Bakst's Life* (1921). (A. LE.)

BAKU, capital of the Azerbaijan Soviet Socialist Republic, U.S.S.R., and fourth city of the Soviet Union, lies on the western shore of the Caspian sea, around the head of the semicircular Baku gulf, on the southern side of the Apsheron peninsula. The gulf, sheltered by the islands of the Baku archipelago, provides the best harbour of the Caspian, while the Apsheron peninsula gives protection from the violent "Baku northers" of winter, when wind speeds often exceed an average of 40 m.p.h. The name Baku is supposed to derive from *Bad-kyy*, "Town of Winds."

The first historical reference to Baku dates from A.D. 885, although there is archaeological evidence of settlement there several centuries B.C. In the ancient fortress of Baku there still survives the mosque Syny-Kala, dating from 1078–79. Also believed to be of the 11th century is the oldest part of the palace of the Shirvan shahs, whose capital was there. From the 12th century dates the 90-ft. tower of Kyz Kalasy. Peter the Great captured Baku in 1728, but in 1735 returned it to Persia. Russia finally captured the town in 1806. In 1920 it became the capital of the new Azerbaijan republic. The population, 2,235 in 1806, rose to 300,000 in 1917 and in 1959 was 642,507 in Baku city itself and 971,058 in the 13 districts of Greater Baku, which includes almost all the Apsheron peninsula under one city council.

The city's great importance lies in petroleum. Some wells occur in Baku itself, but most are on the Apsheron peninsula or out in the Caspian. The presence of oil has been known since early times, but large-scale working did not begin until 1873. Now oil must be obtained at increasingly great depths, down to 16,700 ft. A network of pipelines links the drilling "suburbs" with the refineries and processing plants of the city. Baku exports oil by pipeline to the Batumi refineries or by tanker across the Caspian and up the Volga. In addition to pipe and sea links, Baku has rail connections to Rostov-on-Don and central Russia, to Tbilisi and to Yerevan. Other industries include the manufacture of oil-industry machinery (20 plants) and electrical machinery, shipbuilding and repair, chemicals, and the production of cement, textiles, footwear and food. Industries are located chiefly at the eastern (Black Town) and western (Bibi-Eybat) ends of the city.

Baku is a major cultural centre, with an academy of sciences, a university, a number of other higher educational institutions and eight theatres. (R. A. F.)

BAKU, SECOND: *see* SECOND BAKU.

BAKUFU, the military headquarters and, by extension, the government of the shogun (*q.v.*), *de facto* rulers of Japan from A.D. 1192 to 1868. The term is most commonly rendered "shogunate" in western literature. Three *bakufu* were established: the first by Minamoto Yoritomo (*q.v.*) at Kamakura (1192–1333), the second by Ashikaga Takauji (*see* ASHIKAGA) at Muromachi (1338–1573), and the third by Tokugawa Ieyasu (*q.v.*) at Edo (1603–1868). Legally the *bakufu* exercised authority delegated by the emperor through the office of shogun. This authority was in theory limited to the military forces of the country, but the increasingly feudal character of Japanese society created a situation in which control of the military class became tantamount to control of the country. By the 17th century the *bakufu* exercised civil and military authority over all domestic and foreign affairs; the emperor remained in his palace in Kyōto chiefly as a symbol of sovereignty behind the shogun.

Minamoto Yoritomo set the pattern of *bakufu* organization. In 1185 he gained military hegemony of Japan, and in 1190 received the title General of the Right Imperial Guards. He named his Kamakura headquarters *bakufu*. When in 1192 he became shogun the term *bakufu* became identified with this office. Yoritomo's government was designed chiefly to exercise control over the warrior aristocrats. When possible, however, he sought to enlist members of the warrior class as his housemen, or vassals, bound to him personally by oath and his reciprocal grant of protection over land rights. Eventually most military men of the Kantō region of eastern Japan became his housemen; elsewhere his vassals were more thinly scattered among military houses still loyal to the imperial court or the great Buddhist monasteries.

The Kamakura *bakufu* had a central administration consisting of a chief administrator, a military office, an administrative office and a judicial office. Some officials were delegated as superintendents with specific functional duties. Outside of Kamakura the *bakufu* maintained deputies and garrisons in Kyōto, the imperial capital, and in northern Kyushu. *Bakufu* authority in the provinces was based on two classes of officials. Military governors (*shugo*), selected from among the shogun's more powerful housemen, assumed supreme military and police powers in each province. Land stewards were assigned to military and fiscal affairs of the separate estates into which the provinces were divided. This combination of central headquarters and the system of military governors and stewards provided an effective nationwide administrative network centred on Kamakura. The *bakufu* functioned as a government for much of Japan, although the imperial government and its related religious institutions still held the

preponderance of territory and continued as the recognized legal government.

Ashikaga Takauji attempted to revive the *bakufu* form of government after the fall of Kamakura in 1333. The provincial military houses, chiefly *shugo*, however, had come to dominate military and civil affairs within their respective provinces. Although the Ashikaga family secured the allegiance of these *shugo* houses, its hold over them was insecure. The Ashikaga *bakufu* served as the centre of a precarious coalition between the uncertain central authority of the shogun and the increasingly powerful and independent *shugo* houses. To assure control of the emperor, the shogun established his headquarters in Kyōto. A chief administrator, selected from among the most loyal *shugo*, was placed under the shogun in Kyōto. Provincial administration was delegated entirely to the *shugo*. In the Ashikaga *bakufu* the important central posts were also taken by *shugo*, creating the precarious condition in which powerful local families could dominate the shogun. The establishment of the *bakufu* in Kyōto and the extension of *shugo* powers in the provinces brought to an end the political power of the emperor and the imperial bureaucracy. By the 16th century, as the Ashikaga *bakufu* lost its power to govern Japan, the country became divided into the private domains of local magnates, the successors of the *shugo*, known as daimyo (*q.v.*).

In 1600 Tokugawa Ieyasu gained hegemony over the daimyō thus laying the foundation for the third shogunate. The Edo *bakufu* was much more soundly built as an effective national government. The shogunal domains comprised about one-quarter of the entire country and embraced all the important cities. The shogun's private housemen numbered over 22,000 men. Of the nearly 200 daimyo, joined to the shogun by oath in 1614, nearly one-half were either kinsmen or former housemen.

The Tokugawa *bakufu* functioned at two main levels. On the one it maintained a machinery of control over the emperor, the daimyo and the religious establishments; on the other it provided an administration for the management of its lands and the handling of its national responsibilities. The shogun placed the emperor under a set of restrictions which effectively isolated him from political influence. A *bakufu* military governor of Kyōto was appointed to keep watch on imperial affairs. Daimyo were obliged to pledge allegiance to the shogun's fundamental code, which among its provisions made *bakufu* law supreme in the land and set up the alternate attendance system. Under this system the daimyo were obliged to reside periodically in Edo, leaving their families as hostages when they returned to their domains. *Bakufu* inspectors frequently toured the daimyo domains, which otherwise were made autonomously responsible for local administration.

The administration of the Edo *bakufu* was centred on the great castle of Edo, now the location of the Imperial palace in Tokyo. A senior council of five or six members selected from among the shogun's foremost house-daimyo exercised jurisdiction over foreign policy, general domestic affairs, the affairs of the daimyo, relations with the imperial court and other important matters. A junior council of four or five supervised the affairs of the shogun's retainers and the military guards. Under these councils were a variety of officers with specific responsibilities such as: superintendents of finance, inspectors general, superintendents of temples and shrines, and city magistrates of Edo. Outside of Edo the *bakufu* maintained administrative and garrison headquarters at Sumpu, Osaka and Kyōto. Shogunal magistrates were set over all towns and cities. The magistrate of Nagasaki had the additional duty of supervising foreign trade. The far-flung shogunal territories were administered directly by intendants who reported to the superintendents of finance.

After 1862 the Tokugawa *bakufu* underwent drastic remodeling under French inspiration, but in 1868 the last shogun, Yoshinobu, lost control of the country. The *bakufu*, both in terms of the central administration in Edo and the provincial administrations of the daimyo, provided a foundation for Japan's modern government. *See* also JAPAN: *History: The Development of Feudalism.*

(J. W. H.)

BAKUNIN, MIKHAIL ALEKSANDROVICH (1814–1876), Russian revolutionary agitator, the leading spirit of 19th-century anarchism and a bitter opponent of Marxism, was born at Premukhino, in the Tver province, on May 30 (new style; May 18, old style), 1814, the eldest son of a retired diplomat and landowner. After three years of study as a military cadet in St. Petersburg, he was commissioned in 1832 to serve with an artillery regiment in eastern Poland, but resigned his commission in 1834. He explained to his father that, consumed by boredom, he had resolved to study philosophy and meanwhile to earn his living as a teacher of mathematics. In fact he chose the easier alternative of borrowing money from his generous friends and in 1840 departed for Berlin university, where for a year and a half he studied Hegel. This finally cured him of the "prevailing philosophic disease," as he described it, and in 1841 under the influence of Arnold Ruge, editor of the *Deutsche Jahrbücher*, he turned to revolutionary agitation. Feeling that he had been duped by Hegel, Bakunin now announced that true philosophy ought to be a negation of all philosophy and found for the first time that real religion lay in "political action and the social struggle."

His departure from Berlin marked the start of Bakunin's long career as the mendicant monk of a nonexistent revolutionary church and as a reckless conspirator who aspired to lead an international anarchist army. He met Karl Marx in Paris and complained that Marx corrupted honest workmen by making them cerebral. It may be that the French anarchist Pierre Proudhon, whom he also met, gave him his pet idea of federal republics springing up spontaneously from below and putting an end to all sovereign states and wars between them, but Bakunin transformed this into his own favourite project for a vast Slavonic federation to replace the Austrian and Russian empires.

Bakunin took an active part in the Paris rebellion of 1848 and the Dresden insurrection of 1849. He was arrested in Dresden on May 10 and sentenced to death, but in 1851 was handed over to the Russian government. In the Petropavlovsk prison he wrote an abject confession of his political crimes and madness, for the benefit of the emperor Nicholas I. Transferred to a penal settlement in eastern Siberia in 1857, he escaped in 1861. Through Japan and the United States he made his way to London, where he started to write for A. I. Herzen's free Russian journal *Kolokol* ("The Bell").

The failure of the Polish rising in 1863 marked a major practical *débacle* for Bakunin. Henceforth he became absorbed in a campaign for universal anarchy. In 1865 he started schemes for a worldwide organization, a so-called International Brotherhood, divided into "national families" but secretly controlled by an "international family." He described the state socialism of his rival Marx as "the vilest and most formidable lie which our century has engendered, official democracy and red bureaucracy." From 1868 Bakunin's struggle with Marx to win leadership of the International Working Men's association (known as the First International) began in earnest. He tried to get his own International Social Democratic alliance incorporated into the International. In the controversy that ensued between Marx and him the charge of concealed dictatorship, which both hurled at one another, was more substantially true about Bakunin. Marx accused Bakunin of violating his obligations as a member of the International by founding a secret society with statutes hostile to it.

In his pamphlet *The Knouto-German Empire and International Socialism* (1871), Bakunin identified the Marxian German school of socialism with the worst religious and political despots of the past, those who had tried to make a school of thought the sole source and guide of living. He identified every strong state with a despotic lust, bound to mutilate its subjects mentally and morally. A weak state, he grudgingly admitted, might be virtuous, but he believed that the days of nation-states were numbered. He pointed out that former manual workers, once they had become rulers and representatives, tended to despise the so-called working class.

After the Franco-German War, during the rebellion at Lyons, which started a short-lived local commune, Bakunin rushed to throw in his lot with the insurgents. The cruel lesson taught him by his disciple, the sinister S. G. Nechaev (1847–82), who in 1872 murdered another of Bakunin's pupils for betraying their cause, seems to have shattered Bakunin's more ambiguous revolutionary

beliefs. Meanwhile Bakuninist "cells" were spreading within Russia, and outstanding Narodniki like P. B. Akselrod and Vera I. Zasulich claimed to be his followers. But though Bakunin influenced many Russian revolutionaries and had devoted followers in Italy and Spain, his repeated attempts to organize revolts had all failed.

While remaining a militant atheist, Bakunin seems ultimately to have lost his old faith in spontaneous popular insurrection as the only sure method of destroying state governments. He died at Bern, Switz., on July 1, 1876. There is an edition of his collected works, in Russian, edited by Y. Steklov, four volumes (1934–35).

See E. H. Carr, *Michael Bakunin* (1937); Richard Hare, *Portraits of Russian Personalities Between Reform and Revolution* (1959).

(R. Ha.)

BALA (Y Bala), a market town and urban district of Merionethshire, north Wales, lies 40 mi. S.W. of Chester by road. It is near the confluence of the Tryweryn and the Dee, at the outlet of the latter from the northern end of Bala lake, the largest natural lake in Wales (*bala*, Welsh for "outlet"). Pop. (1961) 1,604.

The name Bala was originally given to a fortified mound of the motte-and-bailey type, still known as *Tomen-y-Bala*, the biggest of a series of such mounds at strategic positions along the upper Dee valley. The town was founded in the 14th century as a market centre and its burgesses were granted trading rights and protection against the warlike tribesmen of Penllyn. By the 18th and 19th centuries it had become a prominent centre for woolen cloth, especially flannel and hosiery. From the 18th century it also became a centre of Welsh cultural and religious activity. Eisteddfodau were held in the taverns, and the printing presses produced important works in Welsh prose and verse. A grammar school was founded in 1712 and a Calvinistic Methodist college in 1837, both of which are active. Great Methodist assemblies were formerly held on "the Green." Statues in the town commemorate Thomas Charles (Charles of Bala, 1755–1814), Methodist divine and one of the founders of the British and Foreign Bible society; Lewis Edwards (1809–87), theologian, educationalist and man of letters; and Thomas Edward Ellis (1859–99), Liberal leader and patriot. Elizabeth Davies Jones (1789–1860), pioneer nurse, and Michael D. Jones (1822–98), promoter of a Welsh colony in Patagonia, were born there.

The first sheep dog trials in the country were held there in 1873 and still take place annually. There is good grouse-shooting and fishing, including salmon, trout and the white-scaled gwyniad peculiar to Bala lake. Flooding in the Dee valley was checked by widening and deepening the channels at the head of the lake.

(T. H. Wi.)

BALAAM, a non-Israelite prophet in the Bible, who was asked by Balak, king of Moab, to curse Israel. The main passage about Balaam is in Num. xxii–xxiv, and consists of material from the Yahwist (J) and Elohist (E) traditions (*see* Pentateuch), together with seven poetic oracles and a few editorial additions.

The Yahwist narrative and its associated poems (indicated below by numerals in italics) is found in Num. xxii, 3b–7 (omitting the words "at Pethor, which is near the River" in verse 5), 11, 17, 18, 22–35a, 36a, 39; xxiv, 1, 2, *3–9*, 10–14, *15–19, 20, 21–22, 23–24,* 25. Balak, alarmed at the rapid advance of Israel, and having heard of Balaam's efficacy in benediction and malediction, sends emissaries to him with adequate payments and the request that he come and curse Israel. Balaam states that he will be able to speak only what Yahweh inspires, but accompanies the messengers to Balak. An angel of Yahweh meets him on the way, seen by his ass, but not by himself. When finally Yahweh opens Balaam's eyes, he allows him to continue his journey. Balak meets Balaam, who, after seeing Israel, blesses its people. Balak remonstrates with him, but Balaam blesses them again. Indeed Balaam blesses Israel three times, and returns home. The poetic oracles embedded in the J narrative celebrate the glory and conquests of the monarchy (xxiv, 3–9) and announce the coming of a king (possibly David) who is to conquer Edom and Moab (xxiv, 14–19).

The E narrative with its associated poems is found in Num. xxii, 2, 3a, 5b (*i.e.,* the words "at Pethor, which is near the River"), 8–10, 12–16, 19–21, 35b, 36b–37a, 38, 40, 41; xxiii, 1–6, *7–10,* 11–17, *18–24.* Balak sends princes to invite Balaam to his maledictory task. God appears to Balaam in a dream and forbids him to go to Balak, and the princes are therefore sent back. In another dream God permits Balaam to go to Balak, on condition that he speak only what God imparts. Balaam communicates this condition to Balak when they meet. Balak offers sacrifices, but Balaam is constrained to bless Israel. Balak remonstrates, is reminded of the divine condition of Balaam's prophesying, and then proceeds to sacrifice again, evidently seeking the possibility of a differently toned prophecy. But again Yahweh constrains Balaam to bless Israel. After further expostulation and explanation Balaam returns home. The two poems woven into the Elohist narrative tell of the unique exaltation of Israel (xxiii, 7–10) and extol the moral virtue of Israel, its monarchy and its conquests (xxiii, 18–24).

In the light of later developments of the tradition it is interesting to note the differences between J and E. In J, Balaam sets out willingly enough with Balak's messengers, though he tells them that his prophetic utterances will be limited to what Yahweh inspires. On the journey he is met by an angel of Yahweh (*i.e.,* Yahweh himself in theophany) who, having indicated divine displeasure with Balaam's decision to accompany Balak's messengers, permits him to continue provided that he speaks only what Yahweh commands. In the event, Balaam is faithful to Yahweh and blesses Israel. In E there is a slight contrast, for Balaam is first forbidden to accompany the Moabite princes, but later is permitted to join them. In his mission for Balak he is, as in J, faithful to Yahweh in actual utterance, though he seems to acquiesce in the second sacrifice by Balak, and thus in his desire to receive other than a benediction for Israel. It would seem that this is a beginning of a denigration of the character of Balaam.

This tendency continues. The reference to Balaam in Deut. xxiii (D), 3–6, condemns both Ammonites and Moabites for hiring Balaam to curse Israel, and adds the comment "but the Lord . . . turned the curse into a blessing," a not wholly unambiguous reaffirmation of the tradition that Balaam uttered nothing but blessings upon Israel. Josh. xxiv, 9, 10 (E) reads as if Balaam uttered a blessing upon Israel only when malediction had not been endorsed by Yahweh. The Priestly tradition (Num. xxxi, 8, 16) states that Balaam advised the Midianites how to bring Israel to idolatry at Baal-Peor, and that he was later slain in battle.

By New Testament times Balaam had become the type of avarice (II Pet. ii, 15, 16; Jude 11) and of enticement to idolatry (Rev. ii, 14). Jewish tradition shared this denigratory trend. It seems that a later Jewish exclusiveness caused the earlier virtue of Balaam to be overshadowed; and it is therefore the more important that the evident appraisal of both J and E should be restored: that Balaam is an outstanding and early example of the truth that God remains sovereign in his freedom to call to his service whomsoever he will.

(Jo. M.)

BALADHURI, AL- (Ahmad ibn Yahaya) (d. 892), one of the earliest Arab historians, and the best authority for the period of the formation of the Arab empire, was a native of Baghdad. His chief work, *Futuh al-Buldan*, gives an account of the conquest of Arabia, Syria, Mesopotamia, Armenia, Egypt, north Africa, Spain, the Mediterranean islands, Nubia, Persia and Media. A second work, *Ansab al-Ashraf* ("Lineage of Nobles") deals with the genealogies of the early Arab aristocracy.

For Eng. trans. of *Futuh al-Buldan* see P. K. Hitti, *The Origins of the Islamic State* in the Studies in History, Economics and Public Law series of Columbia university (1916). *Ansab al-Ashraf* was ed. by G. Flügel (1835), and part of it was ed. by S. D. F. Goiten and M. Schloessinger, with indices and annotations, 3 vol. (1936–40).

BALAENA, the genus of whales to which the Greenland right whale and bowhead belong. *See* Whale.

BALAENICIPITIDAE, the family of shoebills, or whale-headed storks, placed with herons, true storks, etc. in the order Ciconiiformes. Only one species, the African *Balaeniceps rex*, is known (*see* Stork).

See also Bird; Ornithology.

BALAENOPTERA, the genus name of the group of whales known as the rorquals, finbacks and fin whales. With the closely

allied genus *Sibbaldus* (blue whale, etc.) they form the main object of pursuit in modern whale fisheries. *See* WHALE.

BALAGHAT, a municipal town and district in Madhya Pradesh, India. The town is near the east bank of the Wainganga river, 95 mi. S. of Jabalpur. Pop. (1951) 16,291. It is on the Satpura narrow-gauge line of the Southeastern railway, connecting northward with Jabalpur and southward with Gonda junction (25 mi.) on the main line.

BALAGHAT DISTRICT (3,573 sq.mi.; pop. [1961] 806,620) is divided by the eastern Maikal hills from the Chhattisgarh plain to the east. It contains gneissic and metamorphic rocks with a few Deccan trap outliers in the north. The rocks belong to the Gondite series containing slates, phyllites and quartzites, and crystalline manganese oxides, the source of economically important manganese ore. Some hilltops of the central plateau (Baihar) contain important bauxite deposits. The Satpura range, of considerable scenic beauty, crosses the north of the district; the average annual rainfall is 62 in. The forest (comprising 13% of the district's area) is the habitat of nilgai, swamp deer and wild cattle, and yields teak, sal, bamboos, lac and myrobalans (*q.v.*). The forest products are collected by Gond aboriginal tribespeople (*see* GONDWANA) who form one-third of the district's population. There is also a small community of Baiga (*q.v.*) tribesmen (2%), who are skilled woodmen: they make bamboo mats and collect tendu leaves for manufacturing *bidis*, the ubiquitous cheap cigarettes of India. The northern rivers, tributaries of the Narbada, have limited rich soil-areas used for tobacco and sugar cane cultivation. In the Wainganga valley in the south and southwest rich soil-areas are more extensive. Rice is the chief crop (about 40% of total sown area) followed by the small millets *kodon* and *kutki*, and pulses. Cattle are raised on the excellent pastures of the Baihar plateau. Waraseoni (pop., 9,556) and Lalburra are cattle markets. (D. G. NA.)

BALAGUER, VICTOR (1824–1901), Spanish writer and politician, who played a major part in the revival of Catalan nationalism during the 19th century. He was born at Barcelona on Dec. 11, 1824, and educated at the university of his native town. Most of his early life was spent in encouraging the development of local patriotism. He wrote for several newspapers and produced poetical works in Catalan, the first being the *Oda á la Verge de Montserrat* (1857). A few years later he moved to Madrid, but his political views were too progressive and he was obliged to emigrate to Provence. Returning after the revolution of 1868, he became a member of the constituent *Cortes* in 1869 and minister for colonies two years later. Subsequently he became president of the *Tribunal de Cuentas* and president of the Council of State. He died at Madrid on Jan. 14, 1901.

Outside Catalonia he is remembered mainly as the author of *Historia de Cataluña y de la Corona de Aragón* (1860–63), but although he has few literary merits other than those of a pioneer, his works did great service for the cause for which they were written and in Catalonia his name will endure.

BALAKIREV, MILI ALEKSEEVICH (1837–1910), Russian composer of orchestral music, piano music and songs, and dynamic leader of the nationalist group in the third quarter of the 19th century, was born at Nizhni-Novgorod on Jan. 2, 1837 (new style; Dec. 21, 1836, old style). His early musical education was received from his mother, John Field's pupil Alexander Dubuque and Karl Eisrich, music-director to A. D. Ulibishev, author of well-known books on Mozart and Beethoven. Balakirev had the use of Ulibishev's music library and at 15 began to compose and was allowed to rehearse the local theatre orchestra. From 1853 to 1855 he studied mathematics at the University of Kazan and wrote, among other things, a piano concerto. In 1855 Ulibishev took him to St. Petersburg and introduced him to Glinka and other leading musicians.

During 1857 to 1859 Balakirev made a number of appearances as a concert pianist, composed an *Overture on Russian Themes*, music to *King Lear* and his earliest published songs, and became the mentor of two young officers who were amateur composers: C. A. Cui and Mussorgsky. During 1861 and 1862 his circle of disciples was joined by Rimski-Korsakov and Borodin, and in 1862 he threw himself into a new venture, the Free School of Music, opened by G. Y. Lomakin in opposition to the St. Petersburg conservatory, and soon became principal conductor of its public concerts. During the 1860s Balakirev was at the height of his influence and his varied activity. He collected folk songs up and down the Volga, published them and introduced them in a *Second Overture on Russian Themes*, which ultimately became the symphonic poem *Russia;* he spent summer holidays in the Caucasus, gathering themes and inspiration for his brilliant piano fantasy *Islamey* (1869) and his symphonic poem *Tamara* (1867–82); he published the works of Glinka and visited Prague to produce them; and for a time (1867–69) he conducted the symphony concerts of the Russian Music society.

His despotic nature and his tactlessness made innumerable enemies, so that even his friends and disciples came to resent his tutelage; and a series of personal and artistic misfortunes led to his almost complete withdrawal from the world of music (1871–76) and his taking a humble post as a railway clerk. He had passed through a period of acute depression ten years earlier; now he underwent a more severe crisis from which he emerged a totally changed man, a bigoted and superstitious Orthodox Christian. He gradually returned to the musical world, resumed the directorship of the Free school, and from 1883 to 1894 was director of the imperial chapel. He also resumed composition, completing works, including a symphony, abandoned many years before, and wrote new ones, including his Piano Sonata (1905), a Second Symphony (1908) and numerous piano-pieces and songs. The last decade of his life was spent in almost complete retirement, and he died in St. Petersburg on May 29 (N.S.; 16, O.S.), 1910.

It has been said that it was Balakirev, even more than Glinka, who set the course for Russian orchestral music and lyrical song during the second half of the 19th century. He developed an idiom and technique—based on the one hand on Glinka, Russian folk music and Caucasian folk music, and on the other on Schumann, Berlioz and Liszt, yet ultimately most personal and idiosyncratic—which he imposed on his disciples (above all on Rimski-Korsakov and Borodin, and to some extent on Tchaikovsky) not only by example but by constant autocratic supervision of their own earlier works. His music is superbly colourful and imaginative, but his creative personality was arrested in its development after 1871 and his later work is couched in the idiom of his youth.

See V. Muzalevsky, *Balakirev* (1938). (G. AB.)

BALAKLAVA (BALACLAVA), **BATTLE OF,** an engagement fought on Oct. 25 (new style; 13, old style) 1854, during the Crimean War (*q.v.*), when British, French and Turkish forces resisted a Russian attack on Balaklava, their supply port on the Black sea, lying about 6 mi. S.E. of Sevastopol. The cavalry charge of the Light brigade, which made the action famous, took place in a valley running in an east-west direction and bounded by the Fedyukhin heights on the north and by the Vorontsov or "Causeway" heights on the south. Russian movement was from the northeast.

In the opening stages of the battle, Russian infantry and artillery occupied positions along the Fedyukhin heights almost unopposed and also forced small, unsupported Turkish forces to retire from artillery strong points along the Causeway heights. The fate of Balaklava depended on about 500 men of the 93rd Highland regiment and on the Heavy (900 men) and Light (670 men) brigades of cavalry. Lord Raglan and his British staff, who had taken up position on the heights above Sevastopol, saw two large-scale Russian cavalry advances—involving about 3,000 men—beaten off, the one by a furious charge of Gen. Sir James Scarlett's Heavy brigade, and the other by the determined stand and disciplined fire of Sir Colin Campbell's Highlanders. From these actions, which undoubtedly saved Balaklava, the Light brigade, under Lord Cardigan (*see* CARDIGAN, JAMES THOMAS BRUDENELL, 7TH EARL OF), held aloof. The Russians then began to withdraw the guns from the captured artillery posts on the Vorontsov heights. Raglan, through an aide-de-camp, issued two orders with the intent of disrupting the Russian removal by means of an attack by the Light brigade. A combination of circumstances resulted in a fatal confusion in relaying the final order, and when

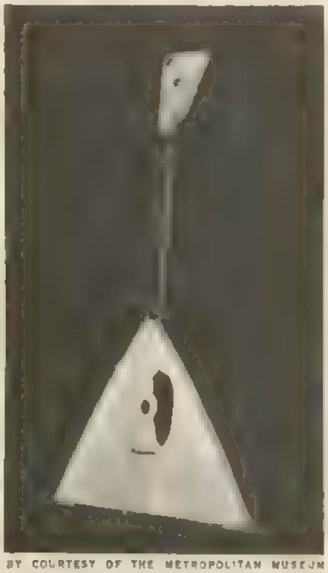
the Light brigade, led by Cardigan, swept forward it moved eastward down the valley between the heights rather than toward the isolated Russian activity on one flank.

Despite heavy loss the charge was completed, leaving an impression of crass stupidity and magnificent courage, which prompted the remark of Gen. Pierre Bosquet, *"C'est magnifique mais ce n'est pas la guerre."* The cost to the Light brigade in manpower was about 40% of the participants. Had it not been for a gallant and timely supporting charge by the French Chasseurs d'Afrique on the Fedyukhin heights the losses might have been even more severe.

There the battle ended. The Russians had not captured Balaklava, but the British had lost control of their best supply road connecting Balaklava with the heights. The legends arising from the charge of the Light brigade, while properly commemorating brave men, have undoubtedly contributed to an overestimation of the importance of the battle of Balaklava. Lord Tennyson immortalized the action of the cavalry in his poem "The Charge of the Light Brigade." (D. M. Sc.)

See F. A. Whinyates, *From Corunna to Sebastopol* (1883).

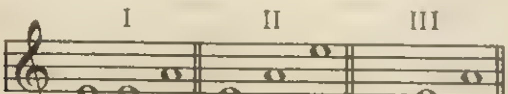
BALALAIKA, a stringed musical instrument. The modern instrument is a sophisticated version of a Russian folk instrument introduced by the musician and impresario V. V. Andreyev of Bejètsk, who made a first public appearance with a band of these improved instruments in 1888.



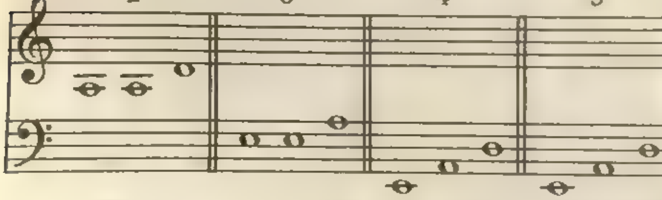
BY COURTESY OF THE METROPOLITAN MUSEUM OF ART, GIFTS OF MRS. JOHN CROSBY BROWN, 1904

RUSSIAN TENOR BALALAIKA, 20TH CENTURY

The balalaika is made in five sizes from treble to double bass, forming a complete, self-contained ensemble. Its characteristic shape is with a triangular table or belly, widest at the bottom and tapering to the neck, and having a small round sound hole in the upper part. The body is vaulted and usually constructed in six sections or ribs, fanning out from the neck to the bottom of the body, which is flat. There are three gut strings, hitched to the bottom and stretched over a pressure bridge. The neck is long and slender, and carries up to 19 metal frets. The type-instrument is the *prima*, tuned in one of the following ways:



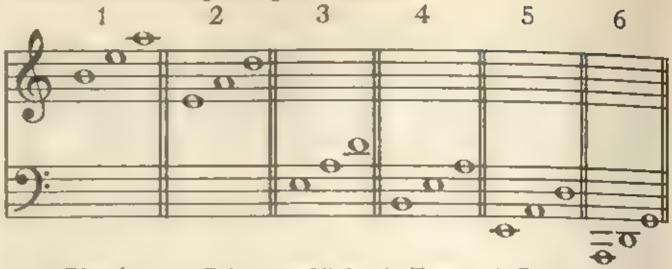
The remaining members of the group, with their tunings, are



2. Secunda 3. Viola 4. Bass 5. Double Bass

The instrument is plucked by the fingers.

To this group Andreyev added another, the oval-bodied domras, also three-stringed instruments strung with gut, which he developed from the ancient prototype found in the Viatka region. The chief difference from the balalaika was the tuning in regular fourths throughout the family and the use of a plectrum. This group also included a sixth member, the diminutive "piccolo" domra. The tunings are given below:



1. Piccolo 2. Prima 3. Viola 4. Tenor 5. Bass 6. Double Bass

(E. HA.)

BALANCE, an instrument for comparing the weights of two bodies, usually for scientific purposes, to determine the difference in mass. The equal-arm types for technical and scientific uses are discussed in this article. Mechanisms for weighing goods and commodities are discussed in the article WEIGHING MACHINES.

The invention of the equal-arm balance dates back to the time of the ancient Egyptians, possibly as early as 5000 B.C. In the earliest types, the beam was supported at the centre and the pans were hung from the ends by cords attached through vertical holes in the beam. This design was improved by drilling the holes so that the end cords were pulled tightly against the ends of the beam by the loads on the pans. A later improvement in design was the use of a pin through the centre of the beam for the central bearing, introduced by the Romans about the time of Christ. The invention of knife-edges in the 18th century led to the development of the modern precision balance. By the end of the 19th century the balance had been developed in Europe into one of the world's most precise types of measuring devices.

The balance consists, essentially, of a rigid beam that oscillates on a horizontal central knife-edge as a fulcrum and has the two end knife-edges parallel and equidistant from the centre. The loads to be weighed are supported on pans hung from bearings, usually planes, supported by the end knife-edges. For the best design two or more additional knife-edges should be located between the end bearing and the pan, one to prevent tilting of the plane and another to fix the centre of load at a particular point on the end knife-edge. An arresting mechanism prevents damage during loading by separating the knife-edges from their bearings. The deflection of the balance may be indicated by a pointer attached to the beam and passing over a graduated scale or by reflection from a mirror on the beam to a distant scale.

Many models of balances have mechanisms for interchanging the loads on the pans without opening the balance case. In some models, the controls can be operated from a distance by means of rods. In each case the rest point of the beam is determined from readings of turning points on the image of a distant scale reflected into a telescope by a fixed prism and a mirror on the beam.

Weighing Procedure.—The most obvious method of using a balance is known as direct weighing. The material to be weighed is put on one pan with sufficient known weights on the other pan so that the beam will be in equilibrium. The difference between the zero reading and the reading with the pans loaded indicates the difference between loads in scale divisions. This difference may be evaluated by comparison with the deflection resulting from a small known weight being added to one of the loads. Such a direct weighing requires that the arms be of equal length. New analytical balances are often required to have the two arms equal within one part in 100,000. With such balances weighings within a precision of about one part in 100,000 can be made by direct weighing methods.

When the error resulting from unequal arms is greater than the required precision the substitution method of weighing may be used. In this method counterpoise weights are added to one pan to balance the unknown load on the other. Then known weights are substituted for the unknown load. This method requires only that the two arms of the beam maintain the same

lengths during the weighing. Any effect of inequality is the same for both loads and is therefore eliminated.

For higher precision the loads should be weighed twice and reversed on the pans for the second weighing. Such a method, known as transposition weighing, in effect makes the balance twice as sensitive as compared with the direct or substitution weighings. Also, if the zero point or the arm ratio is shifting in one direction, then the average of two reversals will tend to eliminate these effects. A series of transpositions may be made to increase the precision.

Since the balance will respond to any force acting on the beam or pans the observer must assure himself as a part of the weighing procedure that any extraneous forces have smaller effects than the required precision. Causes of such disturbances include air currents, heating effects, changes in relative humidity, magnetic influences, vibration, air buoyancy effects, arrestment and release, and swinging of the pans. For precise work the balance should, therefore, be mounted on a rigid support free from vibration in a room with very constant atmospheric conditions.

In many laboratories nonuniform magnetic fields may be caused by electrical equipment or by steel framework in the building. If the balance beam contains magnetic material such nonuniform fields may cause irregular changes in the rest point of the balance. Throughout the dimensions of a balance the earth's field may be considered as practically uniform but not constant. Changes in such a uniform field will not have a translatory effect on the loads or beams but can result in rotation (or torque) provided two magnetic poles in the beam are at different distances from the central knife-edge.

Since the buoyant force of the air affects the balance directly, its effect must be either eliminated or correctly evaluated in order to obtain correct results of weighings. The effect of changes in air density may be reduced by avoiding large differences in volume for the two loads, but for the most precise work the actual volumes and the actual air densities must be used to compute the air buoyancy effects. On brass, for example, the buoyant effect of the air is about $\frac{1}{7,000}$ as large as the force of gravity. Since heating effects will cause convection currents and since the relative humidity changes with changes in temperature, these effects are always intermingled.

Performance of Balances.—Under ideal conditions the highest obtainable precision with the best balances is a little better than one part in 100,000,000 with loads of about 1 kg. The highest relative precision is less than this for both larger and smaller loads. With loads of 20 kg. a precision of about one part in 20,000,000 has been obtained. With loads of 1 g. the limit seems to be about one or two parts in 10,000,000. Such precision can be obtained only with balances of the best designs and under the best conditions. In other cases the possible precision may be restricted by lack of ideal weighing conditions and by improper design.

Weighings of high precision are useful in proving the constancy of standards of mass, and in such problems as determining whether mass changes by appreciable amounts as a result of chemical reaction, or whether the mass of a crystalline structure changes as the crystalline structure is rotated to different positions with respect to its velocity through space.

Standard Weights.—For reference standards of the highest precision the best material is still considered to be the alloy of 90% platinum and 10% iridium used by the International Bureau of Weights and Measures for the international kilogram and the various national prototype kilograms. Retests show that these standards can be relied upon to remain constant for many years within a few parts in 100,000,000.

Standards to be used to check brass or bronze weights should preferably be of about the same density as the weights under test in order to avoid troublesome computations of air buoyancy effects each time they are used. Brass or bronze that is free from holes or pits and plated with gold, platinum or rhodium may make very good standards. The alloy of 80% nickel and 20% chromium has proved to be very satisfactory; but because of difficulty in machining, weights of this material are not ordinarily available.

One-piece weights with their volumes determined by hydrostatic weighings are generally required for work of an accuracy of one part in 1,000,000 or better, but weights of screw knob construction may be entirely satisfactory for less accurate work.

Both lacquered weights and electroplated weights of screw knob construction may prove to be variable with changes in the relative humidity of the air. Most lacquers absorb appreciable amounts of water but are free from the extremely large variations found when electroplating salts are left under the knobs of plated weights. Well-made plated weights are, however, generally less variable with humidity changes than well-made lacquered weights.

For fractions of a gram, weights of platinum and tantalum are superior to those of gold because of the poor wearing qualities of gold. Aluminum is a satisfactory material for the smaller fractional weights.

Design of Beam.—The beam should be designed so as to provide, with a minimum of weight, a rigid support for the three knife-edges. The forces acting on a balance beam are illustrated in fig. 1. The forces exerted by gravity on the mass of the beam and on the two loads are M_1, L and R. The resultant of L and R is M_2 and is so located that $LX_3 + RX_4 = M_2X_2$.

In order for the balance to be in equilibrium, M_0, the resultant of M_1 and M_2 on the vertical Y axis through C, must be located below C. If either M_1 or M_2 is located far enough above C so that M_0 is also above C, there will be no restoring force to bring the beam into equilibrium and the beam will not oscillate. In order to avoid erratic behaviour M_1 should be far enough from the fulcrum C so that the changes in distance resulting from irregularities in the fulcrum are small in proportion to the distance between M_1 and the fulcrum. The point M_2 is brought near the vertical Y axis by equalizing the two loads.

The sensitivity of the balance may be defined as the change in rest point for unit mass added to one of the loads. If a small weight be added to the load R the resulting force will tend to rotate M_1 and M_2 to new positions about C. The sensitivity depends, therefore, on both M_1 and M_2. The effect of M_1 on the sensitivity is independent of the load on the pans. The force M_2 is the resultant force of the loads on the end knife-edges and changes with the loads. In the ideal balance, A, B and C lie in the same plane and A and B are equidistant from C. In this case, with equal loads on the pans M_2 is located at C, and X_2 and Y_2 are equal to zero. Rotation, therefore, does not change the position of M_2 and the sensitivity is entirely dependent on M_1, being constant for all loads.

Discrepancies between repeated rest points for the same loads are necessarily caused by any shift in the position of M_1 or M_2 with reference to the three knife-edges. Refinements in design should, therefore, be directed toward locating the loads in exactly the same places each time the arrestment is released.

The period or time of one swing to and fro of the balance is determined by the arm length of the beam, mass of the loads, mass of the beam and moment of inertia of the beam. The longer

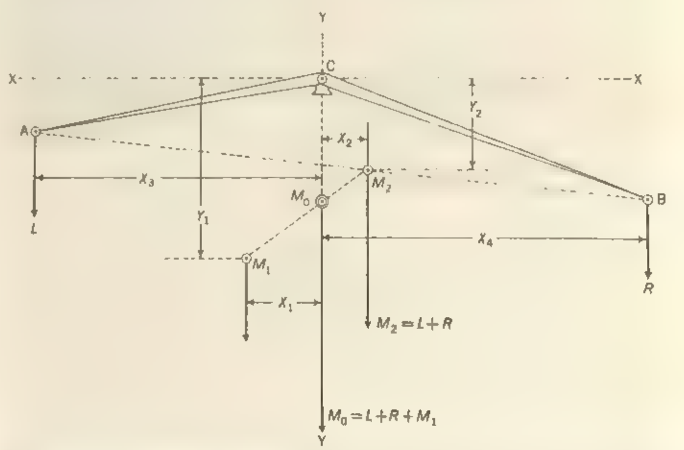


FIG. 1.—FORCES ACTING ON A BALANCE BEAM THAT IS IN EQUILIBRIUM. (*See* TEXT)

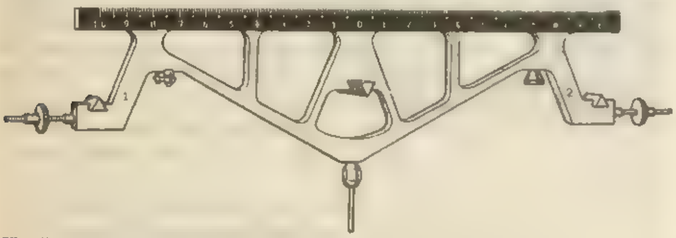
the arm length and the heavier the load the greater will be the period. For a particular balance with constant loads the period is also inversely proportional to the square root of the sensitivity. It is desirable that the material for balance beams should have great strength, a great modulus of elasticity, a low density, a low coefficient of expansion, a high specific heat, high thermal conductivity, and it is essential that it be nonmagnetic. In selecting a material some compromise must be made. Consideration of densities and moduli of elasticity indicate that a beam of aluminum alloy should be more rigid than a beam of copper alloy of the same weight and same length of arms. The effect of large coefficients of expansion of aluminum alloys is offset to some extent by the high specific heats of such materials. Copper alloys, on the other hand, will have a smaller surface to absorb heat, a smaller coefficient of expansion and a greater thermal conductivity. They can, therefore, be expected to equilibriate more quickly from thermal disturbances than aluminum alloys. Another consideration of prime importance is that the material must maintain its dimensions with great accuracy over a period of years. Beams constructed of aluminum alloys and also of copper alloys in balances at the national bureau of standards have shown changes in the ratio of the arms averaging from one to four parts per 1,000,000 per year, and in some cases continuing for more than 25 years.

The material finally selected by the German Normal-Eichungs-Kommission is a type of magnalium that consists of about 86% aluminum, 13% magnesium, and impurities of silicon, iron and copper. A. H. Corwin, however, recommends a copper-beryllium alloy that contains about 95% copper, 4% beryllium and 1% nickel. Brasses, bronzes and various alloys of aluminum have been used. Typical beams for analytical balances are shown in fig. 2 and 3.

Pivots, Knife-Edges and Bearings.—Since the beam rotates through only a few degrees it is possible to combine in the pivots the strength of a large shaft and the frictional effects of a very small shaft. This is accomplished by grinding two optically flat



BY COURTESY OF WM. AINSWORTH AND SONS, INC.

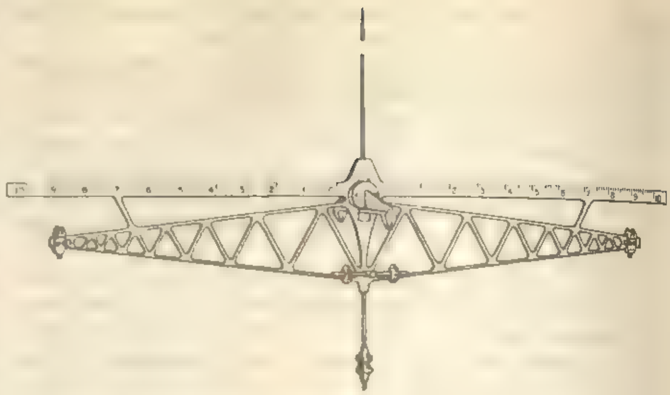
FIG. 2.—BALANCE BEAM OF 200 G. CAPACITY

planes along one edge of a block, usually of triangular shape, the intersection of the two planes forming the knife-edge. Such a knife-edge becomes rounded under pressure. The end bearings may be curved or grooved so that they will not slide off the knife-edge, but for most accurate results the bearing must have a plane surface. Such plane bearings and the planes forming the knife-edge can be constructed with very great accuracy, and their flatness can be easily tested by interference methods with small optical flats. When plane bearings are used it is necessary that the beam and bearings be supported by the arrestment while loading and unloading the balance.

The knife-edges may be adjusted to the proper position by screws bearing on the pivot or they may be wedged into the beam and their position adjusted by bending or twisting parts of the beam. Strains set up in this way frequently cause slow changes in the position of the knife-edges that may continue for years.

Another method, devised by A. Hasemann of Berlin, is to grind the end knife-edges after the pivots are fastened to the beam. This apparatus can be adjusted so that by reference to an accurately flat bed the grinding of the planes will be stopped at the proper places so as to produce a beam with equal arms and with constant sensitiveness for all loads.

The material for the pivots and bearings must be hard and durable. Steel has been used for pivots in the finest balances



BY COURTESY OF NATIONAL BUREAU OF STANDARDS

FIG. 3.—BEAM OF ASSAY BALANCE OF 1 G. CAPACITY

in spite of the danger that it might become magnetized. Agate has been much used for both bearings and pivots but has the serious disadvantage that it is hygroscopic. Pieces of similar size and shape may vary by quite different amounts and may cause the balance to change its rest point with changes in relative humidity and changes in temperature. Corwin recommends boron carbide for both the pivots and plane bearings because it is nonmagnetic, harder than synthetic sapphire or agate, is not hygroscopic, and is claimed to maintain a sharp edge much better than agate.

As the balance swings, successive swings become shorter because of friction. The amount of falling off for successive swings has long been recognized as being proportional to the velocity. Since the period remains constant for deflections of different amplitudes the falling off is also proportional to the length of the swing. The ratio of the lengths of successive swings in the same direction is known as the damping constant. The logarithm of the damping constant is useful in computing the mean rest point and is known as the logarithmic decrement. This kind of damping is found with liquids, gases and magnetic and electrical fields. If the bearing friction were due to solid-to-solid contact it might be supposed that the friction would follow some other law. Experiments by Harald Rossi at Johns Hopkins university have indicated that a moisture film separates the knife-edge from the bearing. These experiments offered the first explanation of the fact that knife-edge friction obeys the same laws as the friction of liquids and gases.

Intermediate Suspensions.—It is not possible to construct a balance beam with the end knife-edges exactly parallel to the fulcrum. Improper design or construction of the intermediate suspensions between each end pivot and pan allows erratic and systematic errors to occur because of the skew position of the end knife-edges or because of tilting of the end bearing. The purposes of the intermediate suspensions are, first, quite obviously, to transmit the load from the pan to the end bearing; second, to prevent tilting of the bearing; third, to prevent erratic shifting of the centre of load along the skew end knife-edge; and fourth, to minimize the systematic effect of skew end knife-edges with motion of the beam.

The centre of load on the end knife-edge is the point vertically above the centre of gravity of the load. Points A and B, fig. 1, are located at the centres of load on the end knife-edges. If the end bearing were fastened rigidly to the pan, then shifting the load on the pan parallel to the end knife-edge would result in a corresponding shift in the centre of load. This effect is avoided by including an intermediate knife-edge in the suspension perpendicular

FIG. 4.—ARRANGEMENT OF KNIFE-EDGES TO AVOID SHIFTING OF CENTRE OF LOAD

The intermediate knife-edge, YY, fixes the load on the end knife-edge XX at the point vertically above YY

to the end knife-edge as in fig. 4.

Under the pressure of the end bearing, the knife-edge takes on a rounded form and has a narrow strip of contact with the plane bearing. With tilting of the bearing this narrow strip wanders along the tilting plane surface with both horizontal and vertical components of motion. This effect, while small, is appreciable in balances of moderate or higher precision and causes changes in the position of M_2 (fig. 1). The tilting of the end bearing is prevented by locating another intermediate knife-edge, ZZ, parallel to and directly below XX as shown in fig. 5.

If, as an experiment, the reader will mount on the circumference of a wheel a crosspiece which is definitely askew with reference to the axle of the wheel and then examine the motion of the skew crosspiece with rotation of the wheel it will become apparent that the skew crosspiece tilts continuously as the wheel rotates. Similarly the skew end knife-edge, XX, tilts continuously as the beam swings. This tilting produces a rotation of the stirrup that hangs in a vertical plane from the end knife-edge. If the intermediate knife-edge, YY, is separated vertically from the skew end knife-edge, XX, then rotation of the stirrup with motion of the beam will cause systematic shifting of the vertical from YY along XX. This causes systematic complications of the sensitivity because of the changes in arm length and in the distance from M_2 (fig. 1) to the fulcrum, C. This effect is eliminated by making the vertical distance between XX and YY equal to zero, that is, by locating them in a common plane.

In order to be stable ZZ must be located below XX. The imperfections in the knife-edge ZZ will cause slight shifting; therefore ZZ should be far enough below XX to minimize any such effect.

Neglect of proper design of the loose joints in the suspension is often the source of large errors in analytical balances. Although the principles involved have long been known, having been developed mathematically by Max Thiesen of Berlin in 1883, it is the exception rather than the rule for the pan suspensions to conform to the theoretical requirements. Other designs of suspensions have proved satisfactory.

In practice it is common to minimize the effect of shifting of the vertical from YY along XX by adjusting the XX axis accurately parallel to the central knife-edge. This may be satisfactory unless strains left in the beam cause the knife-edges to become askew. The substitution of cylindrical pins for the YY and ZZ knife-edges is, however, to be deplored since this type of joint develops appreciable friction under loads. The resulting stiff joints permit shifting of the centre of load and tilting the plane with resulting inaccuracies.

Arrestment.—As was shown above, if the stirrup be shifted in any direction on the knife-edge, the position of M_2 will be changed with resulting changes in arm length and sensitiveness. Therefore a primary purpose of the arrestment mechanism is to replace the bearings and knife-edges precisely in the same position each time.

In balances of the highest precision the pans, stirrups and beam are all supported. With balances of medium precision or better, all three bearings are separated from their knife-edges while in less precise balances the central bearing alone may be separated. In the more precise types the central plane bearing is rigidly mounted and the beam and stirrups are raised to the arrested position by a group of supporting points.

FIG. 5.—ARRANGEMENT OF KNIFE-EDGES TO ELIMINATE TILTING OF END BEARING

The knife-edge YY fixes the centre of load at one point on the skew end knife-edge XX. Knife-edge ZZ prevents tilting of XX

In the type with a single horizontal arrestment arm that moves vertically the arrestment and release occur in the following order: (1) the stirrups are lifted; (2) the beam is lifted; (3) the beam is lowered onto the central bearing; (4) the stirrups are lowered onto the end knife-edges.

The best order to be followed in the arrestment and release is a controversial matter. The single-arm type is, however, generally considered deficient for several reasons. For example, during arrestment and release when the beam rests on the central knife-edge with the end bearings still supported by the arrestment, the end knife-edges may chatter or bounce against the end bearings with resulting damage. Also since the beam is free to oscillate as the end bearings are lowered on to the knife-edges, contact may not occur in the same line on successive releases. Another deficiency arises from the fact that the arrestment falls away from the stirrups along a vertical path while the end of the beam follows a circular path about the fulcrum. If the first contact between the arrestment and stirrup occurs with the beam tipped from the horizontal there will be a tendency to slide the bearings sideways on their knife-edges into the vertical line of motion of the arrestment contact points. With this sequence it is an advantage to arrest the pans first, bringing the beam into a horizontal position before it is arrested. This sequence, 1, 2, 3, 4, is used with the additional precautionary provision that the loads are lifted from the pans by the transposing mechanism before the stirrups are lifted and replaced after the stirrups are lowered on to the end knife-edges. Special care in operation is required with this sequence. In less precise balances the effect of the deficiencies of the sequence 1, 2, 3, 4 may be largely masked by other shortcomings.

The sequence 2, 1, 4, 3 has been considered more desirable and is achieved by separating the arresting mechanism into two vertically moving crossarms, one part for the two stirrups and one for the beam. Many arrestments of this type have contact points for the beam about midway between the centre and end knife-edges. A serious defect becomes apparent when such a balance is accidentally released with only one pan loaded. When this occurs the point of support for the beam nearest the loaded pan becomes the fulcrum, and the beam and stirrups may be thrown violently out of position. This can be avoided by locating points of support for the beam vertically below the end bearings. This sequence necessitates caution to avoid bouncing the loaded beam from one side to the other before the beam is lifted, unless the pan arrest brings the beam into a horizontal position.

In the arc type of arrestment, which is intended to obviate the shortcomings inherent in the single-arm type, two swinging arms are pivoted about a point in line with the central knife-edge. Since the points of contact for the beam are located between the fulcrum and the end knife-edges and have a shorter radius of motion than do the stirrup contacts it is possible to adjust their position so that the beam is arrested first. When this is done the end points will still overtake the stirrups since their greater radius causes more rapid motion. The sequence 2, 1, 4, 3 can, therefore, theoretically be obtained. If, however, the beam is lifted first, then both end bearings must make contact at precisely the same instant; otherwise with a load at only one end, the beam will be tipped and hammering of the knife-edges and displacement of the bearings will result.

The claim has been made that this type of arrestment eliminates any tendency for the bearings and knife-edges to slide during arrestment and release, since the beam and arresting arms rotate about a common axis. This does not necessarily apply to the stirrups, which hang in a vertical plane. The only points on the stirrup that remain a constant distance from the central knife-edge as the beam swings are points on a line with the end knife-edge. If the order of arrestment is 1, 2, 3, 4, then the contact points on the stirrup should be in line with the end knife-edge, a point often overlooked. Use of three points of contact on the stirrup is precluded unless the order 2, 1, 4, 3 is used, or unless the beam is brought into a horizontal position by the pan arrestment previous to the sequence 1, 2, 3, 4.

Since the contact points for the beam follow a circular path the motion is vertical at only one point on the circular path. The contact points on the beam must, therefore, be in the same plane with the three knife-edges if the beam is to be raised vertically from the central bearing. It is very difficult to have this type of arrestment in perfect adjustment. A further dis-

advantage is found in the relatively small central bearing for the swinging arms. Very slight wear will allow the beam and stirrups to be replaced in different positions with successive releases of the arrestment. This type of arrestment is not used in the finest balances.

In one type of arrestment, the stirrups are lifted by three points, which prevents erratic tilting of the bearing plane, the points making contact with a socket, groove and plane, respectively, thereby locating the stirrup in the same position each time. The stirrup arrestment arm is rigidly attached at the back, a flexible section allowing motion and eliminating possible play from loose bearings. The beam has four points of contact with the arrestment, one below each end knife-edge and a socket and groove, respectively, at the two ends of the central knife-edge. The pointer brake, a light wire that touches the pointer during arrestment and release, reduces vibration of the beam. Metal-to-metal contact with resultant sticking is avoided by making the contact points of Pyrex glass.

Quick Weighing Devices.—Various devices are used to speed up the process of weighing. They include adjustable sensitiveness, keyboard-controlled weights, the chain and magnetic damping or air damping.

Sensitiveness can be reduced by a factor of 100 by suspending a highly polished ball from the beam below the central knife-edge. The loads are then balanced to the nearest 10 mg. With the lowered sensitivity the observed difference in scale divisions gives directly the difference between loads in tenths of a milligram. The rider is then set to the correct tenth milligram setting, and the ball removed from the beam. At the increased sensitiveness the difference in scale divisions is numerically equal to thousandths of a milligram. In this way much time is saved by avoiding repeated trials with different rider settings.

Keyboard-controlled weights may be added to a carrier on the stirrup. This device speeds up the weighing process by avoiding disturbing air currents resulting from opening the door of the balance case.

The chain weighing device consists of a chain hung from an additional knife-edge on the beam, with the other end hung from a graduated column or dial adjusted so that the graduations can be read directly in milligrams. Because of errors resulting from friction between links of the chain, time is saved at the expense of accuracy.

By recording turning points, the rest point of a freely swinging balance may be determined at least twice as accurately as with a balance that is damped so as to be dead beat. Since the damped balance must be read a second time to assure that it has stopped moving, time is not necessarily saved by adding such a device to the usual analytical balance. If, however, the period is greatly speeded up and the higher sensitivity obtained by a microscopic scale or other device, then time will be saved.

Microbalances.—Small quartz microbalances with capacities of less than a gram have been constructed with a reliability much greater than is ordinarily found with small assay type balances having a metal beam with three knife-edges. Microbalances are used chiefly to determine the densities of gases, particularly of gases obtainable only in small quantities. Both the torsion and knife-edge types of quartz balance have been used with success. The balance usually operates in a gas-tight chamber and a change in weight is measured by the change in the net buoyant force on the balance due to the gas in which the balance is suspended, the pressure of the gas being adjustable and measured by a mercury manometer connected with the balance case.

In one successful design the beam was suspended from two vertical quartz fibres that take the place of the fulcrum knife-edge used in some earlier types. Hans Pettersson has been able to detect differences in weight of only 0.25×10^{-6} mg. in a load of 250 mg. (L. B. M.)

Guye, "Contributions à l'étude des causes d'erreur affectant les determinations de poids atomiques," *J. Chim. phys.*, vol. 14, p. 25 (1916).

Ultramicrobalance.—The ultramicrobalance is any weighing device that serves to determine the weight of smaller samples than can be weighed with the microbalance; *i.e.*, total amounts as small as one or a few micrograms (1 microgram = 1 γ = 0.001 mg. = 10^{-6} g.). It must show a detectable response to a weight of 0.01 γ or less. The ordinary methods of constructing delicate laboratory balances of the knife-edge type, already discussed, are not satisfactory in the ultramicro range and have been entirely replaced by designs based on other principles. A knife-edge narrow enough to yield necessary sensitivity would have so small an area of contact as to preclude any known material for its construction.

The principles on which ultramicrobalances have been successfully constructed include elasticity in structural elements, displacement in fluids, balancing by means of electrical and magnetic fields and combinations of these. Measurement of the effects produced by the minute masses weighed has been made by optical, electrical and nuclear radiation methods of determining displacements, and optical and electrical measurements of forces used to restore a displacement caused by the sample being weighed.

Simple Elastic Balances.—The preponderance of successful balances has been based on the elastic properties of certain suitable materials, especially quartz fibres, which have great strength and elasticity and are relatively independent of the effects of temperature, hysteresis and inelastic bending. Glass fibres are also useful and were employed before fused quartz became generally available. Elastic balances are advantageous because of their inherent simplicity and sensitivity, and because they measure the weight directly and independently of geographical variations in the gravitational field at the earth's surface.

In 1901 E. Salvioni described a very simple elastic balance constructed from a single glass fibre, mounted horizontally with one end held rigidly, and with a tiny pan suspended from the other (free) end. The application of a load on the pan caused bending of the fibre the amount of which was measured against a stationary scale. Modern modifications of this simple design tend to employ a quartz fibre heavy enough to yield a small amount of bending, the magnitude of which is determined sensitively with a microscope. The weighing range of the Salvioni-type balance is always restricted by the fact that the weight of the pans is usually considerably greater than the weight of the sample. The unloaded pan will then cause a greater deflection than the additional deflection produced by adding the sample to the pan. The subtraction of the large initial deflection from the total deflection leaves only a comparatively small range for the sample, with corresponding difficulty in reading the small movement accurately. The deflection of the fibre caused by its own weight is also quite significant and greater as the length is increased or the diameter reduced.

Quartz fibres, much longer than are practical with the simple design of Salvioni, are often wound into a helix or spring. By increasing both the diameter of the fibre, to increase the possible load, and its length, to increase the sensitivity, greater range of weighing may be achieved. J. W. McBain and A. M. Bakr early constructed such balances manually and employed them extensively in studies of adsorption of vapours on solid adsorbents. P. L. Kirk and F. L. Schaffer developed mechanical means of constructing similar helix balances with superior uniformity of fibre and of helix, and this type of construction was used in commercial helix balances.

Helix balances suffer from some lack of linear response with change of load. Stretching the helix produces moments of both bending and torque in the fibre. Since these moments are not the same function of the diameter of the quartz fibre, and do not retain a constant ratio at different degrees of stretch, a correction must be applied for very accurate weighing. For similar reasons, the helix is somewhat sensitive to temperature differences that also must be corrected for high-accuracy weighing. The helix

balance is therefore of greatest utility for rapid weighings of medium accuracy. It has a relatively high ratio of load to sensitivity as compared with straight fibre balances.

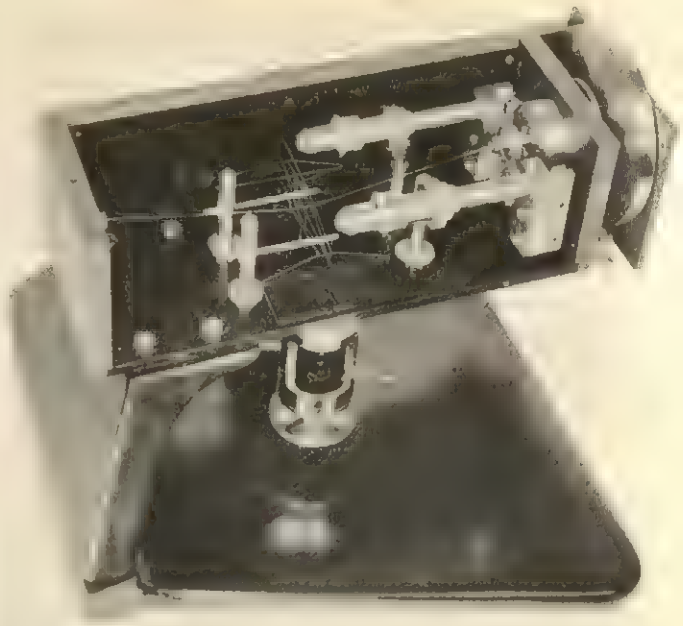
Other designs of simple elastic balances constructed of fused quartz or glass include the flat spiral, which gives an effect similar to an elongated Salvioni fibre but in a compact space, and the quartz circle, which is distorted toward the oval by suspending a weight from its lower portion. If two small mirrors are mounted on opposite sides near the top and facing each other, the distortion produced in the circle serves to deflect greatly a beam of light passed from one mirror to the other in a Z-shaped pattern. This deflection aids in measuring sensitively a very small distortion of the circle caused by the load.

Torsion Balances.—The most successful and practical ultramicrobalances have been based on the principle of balancing the load by applying torque to a quartz fibre. A simple design described by H. V. Neher utilized a rigid fibre as a horizontal beam, supported at its centre by a stretched horizontal quartz torsion fibre sealed to it at right angles. On each end of the beam a pan was suspended, one counterbalancing the other. The deflection of the beam caused by adding the sample to one pan was restored by rotating the end of the torsion fibre until the beam was again in its horizontal position and the full range of torsion in the suspending fibre could be applied to the measurement of the load added to one pan. The amount of torsion necessary for restoration was read by means of a dial attached to the end of the torsion fibre. The weight was obtained by calibrating the balance against known weights, and reading the value from the calibration chart of weight *v.* torsion.

Unlike direct displacement balances that rely only on the elasticity of the structural members, the torsion balance allows gravity to balance the largest component of the load, *i.e.*, the pans, and results in greatly increased load capacity.

The simple design of Neher was limited by: (1) incomplete rigidity of the beam, which allowed some lowering of the centre of gravity with increased load; (2) inexact determination of the rotational position of the beam; (3) uncertainty of the effective beam length; and (4) inexact determination of the amount of torsion. It was also subject to erratic behaviour caused by small air currents resulting from unequal heating by conduction through the case and by radiation through the glass of the case. High sensitivity achieved by using a fine torsion fibre resulted in a large sacrifice of load capacity. With consideration of these limitations of an otherwise favourable principle, P. L. Kirk, R. Craig, J. E. Gullberg and R. Q. Boyer produced a refined version of the torsion balance that became widely accepted as standard for ultramicro weighings and was the model of most ultramicrobalances. Rigidity was increased in the beam without great increase in weight by constructing the beam as a simple truss, 10 cm. in length, with light tension braces from a central vertical support fibre to each end. A second horizontal fibre, parallel to the main beam fibre and only 15 μ in diameter, was mounted on the beam to serve as a sensitive indicator for positioning the beam. Close to each end of this indicator fibre a rigidly mounted microscope objective was focused on the fibre. The images from the two objectives were converged by prisms and brought into a common ocular field so that the two ends of the indicator fibre appeared on the two halves of the visual field of the ocular. The ocular image was projected on a ground glass screen for easy viewing. The beam could be placed in a highly reproducible horizontal position by adjusting its rotation so that the two images were prolongations of each other. Total sag of the beam under increased load did not affect the determination of rotational setting but only lowered both images in the microscope field.

Pans were suspended on fine quartz fibres of the type previously developed by D. Steele and K. Grant as a substitute for knife-edges. Fibres of about 5 μ diameter were sealed at the level of the beam torsion suspension to extensions of the main beam fibre at either end. A fibre of less than 6 μ diameter can be shown to bend so flexibly within a rotation of 1° as to introduce no measurable resistance to the rotation at a sensitivity level of 0.005 γ. Its tensile strength is such as occasionally to support as much as 1 to 5 g. of weight, though not without hazard of fracture. It is, at this diameter, invisible to the human eye and its fusion to the beam must be performed entirely under the microscope. The exact limit of diameter is not immutable and heavier fibres have been employed for carrying heavier loads, but only with some sacrifice of rotational limits or of sensitivity. The fact that the beam is restored to a predetermined setting after loading does not remove the restriction of essential knife-edge behaviour in the pan suspension, since otherwise the beam response is made sluggish and it is no longer possible to set the torsion wheel accurately.



BY COURTESY OF J. RODDER

FIG. 6.—COMMERCIAL QUARTZ TORSION ULTRAMICROBALANCE. (NOTE: THE EXTREMELY FINE QUARTZ FIBRES HAVE BEEN ACCENTUATED)

The torsion fibres and their mounting were highly critical. The diameter required close control because the rigidity of the fibre was approximately a fourth power function of the diameter, whereas the tensile strength was approximately a square function. Very minute differences in diameter gave rise to relatively very great differences in flexibility and consequently sensitivity. A fibre of about 23 μ diameter yielded the usual sensitivity desired, $\pm 0.005\ \gamma$, and reducing the diameter to about 17 μ increased the sensitivity to about $\pm$ 0.001 γ. The fibres were mounted to thickened projections of the beam in two portions, each of about 5 cm. length, one in front and one to the rear of the beam, and at the rotational centre. The rear fibre was supported by a quartz bow of considerable strength which maintained an approximately constant tension on it regardless of the load applied. The bow was held in a spindle mounted in the rear of the case framework, the attachment being made with molten selenium. The spindle was adjustable in a rotational direction or axially with respect to the torsion fibre to permit altering the total tension on the fibre. The front segment of torsion fibre was attached also by a thicker mounting fibre to a wheel by which torsion was applied and its magnitude determined. A suitable wheel was developed from a surveyor's vertical transit wheel by graduating it in a full circle with 2,000 markings. The graduations could be read by vernier to one minute of arc, and required engraving to a somewhat greater degree of accuracy.

Construction of the pans for the torsion as well as for other ultramicrobalances presents several difficulties. They must be strong, noncorrosive and light. Platinum is ideal in its stability and ease of forming, but with a density of 21.5 it is difficult to retain enough strength in a really light pan. The torsion balance was equipped with small platinum pans of about 6 mm. diameter, pressed from 0.001 in. thick foil and weighing about 25 mg. These could also be used as reaction vessels, making unnecessary any transfer in a series of chemical transformations. Pans as heavy as this are not practical for most other designs of ultramicrobalance

for which thin quartz pans are probably most satisfactory. Aluminum foil and even cellophane have been used for pan construction with less favourable types of balance.

On the torsion balance, the pans were suspended from very fine suspension fibres by means of heavier fibres and a quartz stirrup. These suspensions were made long enough so that the pans were held below the floor of the balance case in a metal well equipped with a rotating closure; thus, the pan was accessible without opening the case or disturbing the remainder of the balance. This design was original with H. Pettersson.

The performance of the torsion balance was not seriously affected by vibration because the natural period of the suspension was very different from common vibration periods of the environment and therefore allowed rapid damping of such disturbances. The enclosure of the balance was critical, not because of the balance design but because of the extreme sensitivity combined with high load capacity, which made the balance susceptible to minute air currents caused by minor irregularities of heating. A double case with shielding against conducted and radiated heat maintained uniform temperature. Simple remote control was also installed to avoid direct handling of the balance by the operator with its attendant heat disturbances. Under these conditions the operation was rapid and reliable.

The general design and basic principles applying to the balance described have been utilized in various modifications. The torsion wheel may be moved to the rear of the housing, allowing space for a more direct light path in the optical system with resulting simplification of the optics. The reading and remote control systems are subject to many modifications for convenience or personal preference and the quartz system has been modified for greater load capacity and other reasons.

A number of designs based on similar principles but with significant modifications have been developed. O. H. Lowry described a torsion balance in which no restoration of the beam is employed, but the deflection produced by the sample and opposed by the suspending torsion fibres is measured with a cathetometer. The pans could be counterbalanced, and by avoiding the difficult mechanical construction of the torsion wheel bearings, the construction was greatly simplified. The capacity was 50 to 100 mg. and the sensitivity was 0.1 microgram.

Pettersson described a most ingenious balance in which the beam itself was suspended from fine vertical fibres in a manner similar to the pan suspension described above and which was first utilized by Steele and Grant. His balance did not utilize torsion for restoration of the beam but fine quartz riders were employed for partial balancing, and the residual displacement of the beam was measured.

The sensitivity of the Pettersson balance was of the order of 0.001 γ and the load capacity was comparable with that of the torsion balance of Kirk *et al.*, described above. Its chief limitation was a serious susceptibility to minute vibrations that were transmitted readily through the vertical suspensions. Quartz torsion balances have been constructed inside of relatively large horizontal glass tubes by using very short pan suspensions, and making appropriate modifications in the torsion fibres. Such balances can be operated *in vacuo* or in a controlled atmosphere.

Magnetic Balances.—Following the early magnetic balance of F. Emich and others, a number of delicate balances have utilized a magnetic field to balance a load. The weight is determined in terms of the current necessary to offset the effect of gravity. While such balances have some advantages, they have not been successful in attaining the high load capacity combined with great sensitivity that characterizes the elastic balances. When it is considered that a quartz torsion fibre can restore a load at least 100,000 and possibly nearer to 1,000,000 times greater than the sensitivity with which this restoration can be measured, it is apparent that it is likely to be difficult to apply any other principle as successfully. Measurement of electric current, for example, is difficult when the ratio of total current to the limiting detectable current is greater than 1,000 to 1 and cannot be measured when the ratio is over 10,000 to 1. Since this ratio determines the ratio of the total load to the smallest detectable fraction of the load, it is evident that the load restored will be small as compared with the limiting sensitivity.

Measurement of Deflection.—Numerous procedures other than the use of direct mechanical scales have been attempted in measuring small deflections in elastic types of balance. Some of these are theoretically better than the direct measurement of torsion, *e.g.*, the use of the ultramicrometer which consists of a small condenser with one movable plate controlling a tuned circuit in series with a large capacity condenser. Incredibly small movements of the variable plate throw the oscillating circuit out of resonance, and the alteration in the large condenser necessary to restore the oscillation is a measure of the submicroscopic movement. The practical difficulty of mounting the variable plate to an elastic system subject to variable weight loads had proved unsurmountable as of the sixth decade of the 20th century, but its solution should ultimately increase the refinement of measuring minute masses.

Radioactivity has been employed in determining distortion of elastic systems, by making use of special geometry and some type of Geiger-Müller counter. Since the distance of the radioactive sample from a collector electrode in the counter affects the counting rate, it is possible to so arrange the sample and the electrode that very small movements can be detected and measured. The effectiveness of this device must be considered as questionable in the field of ultramicrobalances for several reasons. The problem of containing safely a sufficient quantity of radioactivity involves masses that are unfavourable.

The emission of the radiation is a statistical function of the atoms involved, and thus a rather large amount of emitting material must be used to guard against random fluctuations in the emission. The necessary arrangements and equipment are also far greater in complexity and amount than is desirable, especially since their presence does not simplify or eliminate the delicate weighing mechanism.

Calibration of all ultramicrobalances is necessary and difficult. Small known weights must be constructed as from wire or quartz fibre using a proportionality factor between length and total weight of the long piece to obtain the small weight. Measured quantities of dilute solutions of known strength may be evaporated to obtain a known solid content. Ultramicrobalances require skill and ingenuity both for their construction and for their operation. *See* GRAVITATION; PHYSICAL UNITS; WEIGHTS AND MEASURES.

BALANCE OF POWER. This term has been used since the 16th century to denote a type of international relations in which one nation or group of nations protects itself against another nation or group of nations by matching its power against the power of the other side. While the term came into general use only in modern times, the practice itself was referred to by ancient writers (*see*, for instance, Demosthenes, *For the People of Megalopolis*, 25 to 32; Polybius, i, 83). The most detailed analysis of the mechanics of the balance of power was written by the Indian political philosopher Kautilya in the 4th century B.C.

As a fact of social experience, the balance of power is a universal phenomenon, by no means limited to international relations. Wherever a number of autonomous social units seek to maintain their autonomy in relation to each other, they must do so by pitting their power, either individually or jointly, against that of their competitors. Thus the U.S. system of government is referred to as a system of checks and balances, and it is said that a certain group in congress, in a political party or in any other kind of organization holds the balance of power.

In international relations, the basic pattern of the balance of power is that of direct opposition between nations *A* and *B*. *A* tries to impose its will upon *B*, and *B* tries to defend itself against *A* and may try to impose its will upon *A*. *B*, in order to defend itself against *A*, must have power at least equal to that of *A*. *A*, in order to defend itself against *B*, must similarly have power at

least equal to that of *B*. An increase in the power of *A* requires a corresponding increase in the power of *B*, and vice versa. Thus both nations, in order to defend themselves against each other, must embark upon a policy of balance of power. They can pursue that policy in two different ways: by increasing their own power—and then they engage in an armaments race or in the competitive acquisition of territory—or by adding to their own power that of other nations—and then they embark upon a policy of alliances.

20th-Century Changes.—The balance of power after the beginning of the 20th century underwent drastic changes that for all practical purposes destroyed the state system as it had existed since the end of the middle ages. During that period, the political world was composed of a number of balance-of-power systems, such as the European, the American, the Indian and the Chinese, which were relatively independent of each other and of which the European was the dominant one. Within the European balance of power, Great Britain played the role of the "balancer" or "holder of the balance." It was not permanently identified with the policies of any European nation. Its only objective was the maintenance of the balance itself. Thus it would throw its weight at one time in this scale, another time in the other scale, guided only by one consideration—the relative position of the scales. Naval supremacy and virtual immunity from foreign attack enabled Great Britain to perform this function, which made the European balance of power both flexible and stable.

The balance of power that emerged from World War II was world-wide in two different respects. All the nations of the world were members of one single balance-of-power system, into which the formerly independent systems were integrated. Furthermore, at the outbreak of World War I in 1914, the main weights in the balance were still predominantly European: Great Britain, France and Russia in one scale, Germany and Austria in the other. At the end of World War II, the principal weights in each scale were either entirely non-European, as in the case of the United States, or predominantly non-European, as in the case of the Soviet Union. The centre of world politics had shifted from Europe to America and Asia.

Bipolarity of Power Following World War II.—This shift in the location of the principal weights in the balance of power went hand in hand with a drastic reduction in the number of the principal weights, until only two weights of the first magnitude were left: the United States and the Soviet Union. Thus there came about what may be called bipolar balance of power. This reduction in the number of first-rate powers greatly affected the operation of the balance of power. The greater the number of active players, the greater the number of possible combinations and the greater also the uncertainty as to the combinations that will actually oppose each other and as to the role the individual players will actually perform in them. Under such circumstances, no player can go very far in his aspirations for power unless he is sure of the support of at least one or the other of his coplayers, and before World War II nobody could generally be too sure of that support. In addition, the approximately equal distribution of power among a multiplicity of nations effectively restrained the aspirations of any one of them.

The bipolarity of power destroyed this restraint that the mechanics of the traditional balance of power imposed upon the principal players. It also destroyed the flexibility that all players formerly enjoyed. Because of the great disparity of power between the two superpowers and all the other nations, the latter lost that freedom of movement that previously had made for a flexible balance of power. Instead, the allies, clustered around the two superpowers, tended to transform themselves into two stable blocs, opposing each other across a rigid boundary line. In these conditions the only element of flexibility stemmed from the ability of the so-called uncommitted nations to join one or the other bloc.

In consequence of these developments, the balance of power, following World War II, had no place for a "balancer," a "holder of the balance." Not only had Great Britain lost the decisive position that it held in the European balance of power for about four centuries, but the concentration of power in the hands of two nations made it impossible for any other nation or combination of nations to perform that decisive function. The result was again loss of restraint and flexibility.

Ideological Struggle.—A final, and perhaps decisive, difference between the post-World War II balance of power and that preceding it lay not in the sphere of the mechanics of power but in the moral realm. Edward Gibbon, in the 18th century, pointed to this factor when he suggested

> . . . to consider Europe as one great republic, whose various inhabitants have attained almost the same level of politeness and cultivation. The balance of power will continue to fluctuate, and the prosperity of our own or the neighbouring kingdoms may be alternately exalted or depressed; but these events cannot essentially injure our general state of happiness, the system of arts, and laws, and manners, which so advantageously distinguish, above the rest of mankind, the Europeans and their colonies . . . In peace, the progress of knowledge and industry is accelerated by the emulation of so many active rivals; in war, the European forces are exercised by temperate and indecisive contests.

This moral consensus was replaced in the mid-20th century by a fierce ideological struggle between two hostile and incompatible political philosophies and ways of life. In consequence, the "temperate and indecisive contests" of times past were replaced by intemperate contests the stake of which was the domination of the world. The old balance of power, while extremely unstable in detail, had sufficient flexibility to survive changes in the distribution of power by adapting itself to them. The new balance of power, while stable in detail, was so rigid that any change in the distribution of power threatened the system itself with destruction.

See ALLIANCE; EUROPE: *History: The Great Age of Monarchy, 1648–1789: Balance of Power;* SPHERE OF INFLUENCE; *see* also references under "Balance of Power" in the Index.

BALANCHINE, GEORGE (GEORGI MELITONOVITCH BALANCHIVADZE) (1904–), Russian-U.S. choreographer, founder and artistic director of the New York City Ballet, was born on Jan. 9, 1904, in St. Petersburg, Russia, and graduated from the Soviet State Ballet school in 1921. During a western European tour, in 1924, he joined the Diaghilev Ballet Russe, and soon became its principal choreographer. His first production was Stravinsky's *Le Rossignol*, which marked the beginning of a long, fruitful collaboration with this composer. For Diaghilev, Balanchine also staged *La Chatte*, *Le Fils Prodigue*, and Stravinsky's *Apollo*, which ranks as a masterpiece.

In 1933, at the invitation of Lincoln Kirstein, Balanchine went to the United States to join him in establishing the School of American Ballet and organizing the American Ballet company, of which the New York City Ballet, established 1948, is the direct descendant.

Balanchine prefers to work in the pure classic dance idiom and many of his finest ballets, such as *Serenade*, *Symphony in C* and *Agon*, have no dramatic themes, but consist of highly original and imaginative dance patterns. Responsible for most of the New York City Ballet's extensive repertoire, Balanchine also created works for the American Ballet Theatre, Royal Ballet, Paris Opéra Ballet and other major companies. A trained musician, he became one of the few choreographers who could read a conductor's score.

In 1964 the U.S. dance world was stirred when the Ford Foundation, awarding nearly $8,000,000 to strengthen professional ballet in the United States, presented the entire amount to the New York City Ballet, its affiliated School of American Ballet, and six other ballet companies—all under the direct or indirect influence of Balanchine. Concern was expressed that a dance monopoly by Balanchine and his followers would be the result.

Balanchine married, successively, five ballerinas: Tamara Geva, Alexandra Danilova, Vera Zorina, Maria Tallchief and Tanaquil

LeClercq, whose brilliant career was cut short by an attack of poliomyelitis in 1956. (Ln. Me.)

BALARD, ANTOINE JÉRÔME (1802–1876), French chemist, best known for his discovery of bromine, was born at Montpellier on Sept. 30, 1802. He graduated from the Montpellier École de Pharmacie in 1826. In 1842 he became professor of chemistry at the Sorbonne and in 1851 at the Collège de France. He died in Paris on March 30, 1876.

In 1824, while studying salt marsh flora, Balard observed sodium sulfate crystals in the mother liquid of common salt. Saturating these bitterns with chlorine and distilling the product, he discovered the only liquid nonmetallic element, bromine (1826). Its resemblance to chlorine and iodine enabled Balard to determine the properties and compounds of this new element. Later he proved the presence of bromine in sea plants and animals.

Although Balard found that the concentration of salts in seawater is low, he correctly pointed out the potential value of the sea as a source of chemicals. He devoted considerable time to the problem of obtaining soda and potash from seawater economically, but his efforts were nullified by the discovery of rich deposits at Stassfurt, Ger., in 1858. Until the discovery of these deposits, all bromine used for photographic plates was manufactured by Balard's method. He also discovered hypochlorous acid and the composition of Javelle water, a bleaching agent. (V. Bw.; X.)

BALASH (Valakhsh), Sasanian king of Iran from A.D. 484 to 488, succeeded his brother Firuz. Threatened from the start by the dominance of the invading Hephthalites (*q.v.*), Balash was able, with support from Zarmihr, a feudal chief, to suppress his rebel brother Zareh. Subsequently abandoned by Zarmihr, he was blinded after being deposed in favour of a nephew, Kavadh. (A. D. H. B.)

BALASHOV, a town of Saratov *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., and from 1954 to 1959 the centre of an *oblast* now abolished, stands on the Khopër river, at the junction of railways to Tambov, Penza, Kamyshin on the Volga, and the Ukraine. The census of 1959 reported a population of 64,349. The good communications and the rich agricultural area around the town have led to the development of food industries. It is the location of a state pedagogical institute. (R. A. F.)

BALASORE, a town in Orissa, India, headquarters of Balasore district, lies 98 mi. N.E. of Cuttack. Pop. (1961) 33,931. The town is 16 mi. up the Budhabalang (Burabalang) river, 7 mi. from the Bay of Bengal. The roadstead and river anchorage attracted English merchants in 1631–34. Their trading settlement, established 1642–51, was followed by those of the Dutch (before 1664), and of the Danes and French in about 1676. The Dutch and Danish settlements were ceded to the British before 1850 but the 38-ac. French holding remained until 1947. Balasore declined as a port in the 18th century because of silting, but became the centre of an expanding rice trade and salt industry. Fakir Mohan college (1944) is affiliated to Utkal university.

Balasore District is an alluvial strip from 9 to 34 mi. broad, watered by six rivers (Subarnarekha, Panchpora, Burabalang, Jamka, Kansabansa and Dhamra), lying between the (Orissa) Nilgiri hills and the sea. Area 2,500 sq.mi. Pop. (1961) 1,415,923. Its natural divisions are: (1) A narrow coastal salt tract rising toward the beach in sandy ridges 50–80 ft. high, extending inland into prairies of long coarse grass and scrub jungle with patches of rice cultivation; (2) the main arable tract, a dry lagoon with level rice fields and depressions near the riverbanks; (3) an undulating submontane tract of red soil cut by ravines skirting the hills and covered with sal jungle. Coastal and high-level canals run the length of the district; intended for navigation between the Hooghly and Mahanadi, they are now mainly drainage canals. The Calcutta-Madras highway and the Southeastern railway from Calcutta (Howrah) serve Bhadrak and other towns. Bhadrak (pop. [1961] 25,285), 39 mi. S.S.W. of Balasore, takes its name from the 4th-century Bhadrakali temple. It also has a college (1948) affiliated to Utkal university, and an engineering school. The only port, Chandbali on the Dhamra river 53 mi. S. of Balasore, is used by coastal steamers. The district, whose population has been decreasing since 1901, exports jute, mats, metal and stone utensils and dried fish. (Ma. M.; N. K. S.)

BALASSI (Balassa), **BALINT** (1554–1594), was the greatest Hungarian lyric poet of his time and remained unrivalled until the end of the 18th century. Born (Oct. 20, 1554, at Zólyom, Hung.) into one of the richest Protestant families of the country, Balassi led a life of adventure, fighting with equal gusto the Turks and his own relatives, out to despoil him of his heritage. He became a Catholic, spent some years in Poland and died of wounds received during the siege of Esztergom (May 30, 1594). At first, his poetry was conventional, but his powerful personality soon broke through the narrow barriers of contemporary humanism and his poetry began to reflect a depth and an intensity of feeling which he had acquired as a result of his experiences. Balassi wrote vividly about the beauty of the countryside, the joys of the dangerous life of a soldier fighting for his country. There is nothing artificial about his later love poems: the feelings are sincere, the expression original. He was the inventor of a stanza form, copied by later poets. Though he knew that happiness was unattainable in this life and peace could be found only in God, he was determined to enjoy to the full what life could offer.

The best edition of his works is by Sándor Eckhardt, *Balassi Bálint összes müvei*, I–II (1951). (Ds. Sr.)

BALATON (Ger. Plattensee), the largest lake (approximately 232 sq.mi.) in central Europe, lies at the foot of the Bakony hills in Trans-Danubian Hungary. It is 48 mi. long from southwest to northeast, but only 9 mi. across at its broadest section: it is almost cut in two by the hilly peninsula of Tihany where it is less than a mile broad. More than 50 streams enter the lake, but the only one of considerable volume is the Zalá at the southwestern extremity. The Sió river on the southern side of the lake connects it with the main stream of the middle Danube. The shallowness of the lake is striking, the maximum depth being only 35 ft. Its level varies considerably, however, with a marked rise in spring due to melting snow and a fall in the dry weather of early autumn. It is completely frozen in winter. The northern and southern banks of the lake are sharply contrasting. The fault-line scarp of the Bakony hills rises steeply to the north with some fine basalt crags near the water's edge, whereas the south bank is flat and sandy with a hinterland of rolling down country in the north and east. On the north side viticulture is a traditional occupation, explained by the rich volcanic soils and by the shelter from the north. On the south side fishing villages are the oldest form of settlement. Both shores attract visitors from Budapest, as the proximity of the lake to the capital has produced a number of summer resorts. Rail and road approaches to the lake are well established. (H. G. S.)

BALBI, ADRIANO (1782–1848), Italian geographer and statistician who was, like C. Malte-Brun (*q.v.*), a successful systematizer and disseminator of the geographical advances of his time and a critical compiler of reliable information and statistics. Balbi was born in Venice in 1782, was first a teacher, visited Portugal in 1820, passed some years in Paris where his books were published, and in 1832 went to Vienna as Imperial counsellor for geography and statistics. He died in Venetia on March 13, 1848. His work was praised by Alexander Humboldt (*q.v.*), and his *Essai statistique sur le Portugal . . .* (1822) remained standard for the rest of the century. His most substantial work, *Abrégé de Géographie . . .* (1832), ran into many editions in a number of languages: an eighth German edition, much enlarged, appeared as late as 1893. The *Abrégé* was much used in the important *System of Universal Geography* published in 1842 and largely written by James Laurie. Balbi's minor works were published by his son Eugenio Balbi (1812–84), professor of geography at Pavia.

See E. Balbi, *Adriano Balbi: ricordi biografici* in *Bollettino della Societa Geografica Italiana* (1881). (A. F. Ma.)

BALBINUS (Decimus Caelius Calvinus Balbinus) (d. A.D. 238), Roman emperor in 238. A patrician, he was a Salian priest under Commodus, consul and proconsul of Asia under Septimius Severus and consul for the second time in Jan. 213 under Caracalla. In 238, when the senate led a rebellion of the Italian cities against

the military emperor Maximinus, it placed the government in the hands of a board of 20, of whom Balbinus was one, and then chose as joint emperors Balbinus and Pupienus Maximus. Maximus, as a former city prefect, was extremely unpopular with the commons of Rome who besieged the senate and its emperors in the Capitol. The situation was saved by associating with the emperors the young Gordian, grandson of the original leader of the revolt, as Caesar.

Balbinus stayed in Rome while Maximus went to defeat Maximinus. When Maximus returned with a German bodyguard, Balbinus quarreled with him, fearing that he intended to make himself sole ruler. The praetorian guards in the city took advantage of the emperors' dispute to kidnap them and, when pursued by the German guards, murdered them both. Gordian was thereupon proclaimed sole emperor. (JN. R. M.)

BALBO, CESARE, CONTE (1789–1853), Piedmontese nobleman whose political writings had an important influence during the Italian Risorgimento was born in Turin on Nov. 27, 1789. He grew up while Piedmont was annexed to France and began his career by entering the Napoleonic bureaucracy. His service in various posts meant that he could later benefit from a wider knowledge of Italy than that of many other Risorgimento leaders. At the restoration of the house of Savoy to the kingdom of Sardinia in 1814 his service to Napoleon was held against him; he himself despised the mediocrity of the restored regime, but though he had friends among the young liberals of Turin, he was loyal to the dynasty. His own views were already marked by a realistic constitutionalism and he disapproved of revolutionary programs. Nevertheless, he fell into disgrace with the regime because of his association with some of the leaders of the 1821 revolution and his attempts to persuade Charles Albert (*q.v.*) to assume the leadership of a constitutional movement. He withdrew for nearly a decade from Turin and began to write. His first book, a justificatory memoir on the events of 1821, was followed by several literary and historical works. His most famous book, *Speranze d'Italia* ("The Hopes of Italy"), appeared in 1844. Its key ideas were that the liberation of Italy was desirable but that the interests of the papacy should be safeguarded and that, after Austria had been compensated in the Balkans, a confederation might be the best answer to Italy's needs. Though this program was patriotic and liberal it was also antirevolutionary, and Balbo's *Lettere di Politica* (1847) called for the formation of a specifically moderate Italian party. His actions in 1848 reflected these cautious views. Charles Albert's grant of the constitutional *statuto* seemed to him to meet the necessary demands for reform, and he became the first prime minister of a constitutional Piedmont (March 13). Alarmed by the democratic agitation of Italy, he resigned in July and was later sent to Gaeta as a Piedmontese emissary to Pius IX. Soon he was defending the temporal power whose abolition he had accepted in 1809. He refused the premiership in 1852 and died at Turin on June 3, 1853.

BALBO, ITALO (1896–1940), Italian soldier and airman, an early Fascist leader who built up the Italian air force between World Wars I and II, was born at Ferrara, on June 6, 1896. He served as an officer in the Alpini (Alpine corps) during World War I and after the war joined the Fascist movement. He was put in charge of the blackshirt militia and in 1922 led the march on Rome. He was made a general of the militia in 1923. He then took a hand in the reorganization of the air force and after becoming a pilot led several long-distance formation flights. He was appointed undersecretary of state for air in 1926, air minister in 1929 and was promoted to marshal in 1933. He was by then becoming unpopular with Mussolini, as he showed friendly sentiments toward Great Britain and was not in favour of co-operation with Hitler. Mussolini also thought that he was becoming too ambitious, and the same year he was sent to Libya as governor general. He was killed in June 1940 when an aircraft in which he was flying crashed at Tobruk, shot down, it was stated, by Italian gunfire after failure to give correct recognition signals. (E. B. BN.)

BALBOA, VASCO NÚÑEZ DE (*c.* 1475?–1519), Spanish conquistador and discoverer of the Pacific, was born at Jerez de los Caballeros about 1475. He was the impecunious descendant of ancient Galician nobility. In 1501 he sailed with Rodrigo de Bastidas, discoverer of the Colombian coast and the northern coast of the Isthmus of Panama, settling thereafter in Hispaniola, the island today occupied by Haiti and the Dominican Republic. Physically striking ("of very gallant mien, and handsome . . . tall, clean-limbed and strong") and a mighty swordsman, Balboa was to prove a great leader and a wise and magnanimous conqueror. As a pioneer farmer, however, he was conspicuously unsuccessful, and in 1510 he escaped his creditors only by hiding in a cask and being carried aboard a caravel carrying reinforcements to Alonso de Ojeda's new mainland colony at San Sebastián on the Colombian coast. Finding Ojeda gone and, of his company, only 41 survivors (led by Francisco Pizarro), the expeditionaries—on Balboa's advice—crossed from Urabá to the less hostile Isthmian coast. There, in Darién, they founded the first stable settlement of continental America: Santa María de la Antigua. By March 1510, Balboa was in command, elected at the expense of two ousted claimants: Ojeda's chief justice, Martín Fernández de Enciso (thenceforth Balboa's implacable enemy), and Diego de Nicuesa (*q.v.*), the governor of Veragua. On Dec. 23, 1510, King Ferdinand V appointed Balboa interim governor of Darién.

During his explorations, Balboa became convinced that the long-sought "Other Sea" with its fabulous kingdoms lay not far distant. He so informed the king, adding that the Indians said its discovery would require 1,000 fighting men. This, and other reports of the riches of *Tierra Firme* (the Isthmus of Panama), inspired creation of an ambitious crown colony (Castilla del Oro); 2,000 new colonists were recruited, and Pedro Arias de Avila, called Pedrarias, was made governor. (*See* ARIAS DE AVILA, PEDRO.)

Warned of his impending replacement, Balboa determined to forestall his successor and himself find the other sea (the *Mar del Sur*, or South sea) before Pedrarias' arrival. Setting out on Sept. 1, 1513, with 190 Spaniards (half the strength of Darién) and 800 Indians, he crossed the Isthmus and on Sept. 25 (or 27), 1513, gaining a hill near the Gulf of San Miguel, he saw the Pacific for the first time; on Sept. 29, he succeeded in reaching the sea at the Gulf of San Miguel and took possession of the "South Sea" and all its coasts for the kings of Castile. Storms prevented a crossing to the Pearl Islands; turning inland, Balboa penetrated almost to the site of present-day Panamá before returning across the isthmus to Darién (Jan. 19, 1514).

Impressed by Balboa's achievement King Ferdinand named him *adelantado* (governor) of the South sea and of Panamá and Coiba. Pedrarias, bitterly envious, contrived to nullify the award, confining Balboa in Darién and harassing his rival in every way possible. Later, forced to license Balboa to return to the Pacific, he prudently married one of his daughters (by proxy) to his hated but potentially important rival, whose departure he delayed until 1517. The marriage, however, did not put an end to the enmity between the two men. Late in 1518, before Balboa could profit by the ships which he and his followers had laboured to build, Pedrarias lured him to Acla and there compassed his judicial murder. Condemned on spurious charges of treason, his right of appeal denied, Balboa was beheaded in Jan. 1519. *See* also PANAMÁ: *History*.

See Kathleen Romoli, *Balboa of Darién* (1953), which contains an extensive bibliography of sources, and C. L. G. Anderson, *Life and Letters of Vasco Núñez de Balboa* (1941).

BALBOA, Pacific terminal port, town and territorial subdivision of the Panama Canal Zone, named for Vasco Núñez de Balboa, discoverer of the Pacific. The town, lying between the docks and Ancón hill, is about 1 mi. from Panamá city, which is not a seaport. Pop. (1960) 3,139. Balboa Heights, adjacent to Balboa, is administrative headquarters for the Panama Canal company and Canal Zone government. The Balboa district (pop. [1960] 30,623, area 222 sq.mi.) comprises the southeast section of the zone. *See* PANAMA CANAL.

BALBUS, literally "stammerer," the name of several Roman

families. Of the Acilii Balbi one, Manius Acilius, was consul in 150 B.C., another in 114. To another family belonged T. Ampius Balbus, a supporter of Pompeius, afterward pardoned by Julius Caesar. We know also of Q. Antonius Balbus, praetor in Sicily in 82 B.C., and Marcus Atius Balbus, who married Julia, a sister of Caesar, and had a daughter Atia, mother of Augustus. The most important of the name were the following two Cornelii Balbi, natives of Gades (Cádiz).

Lucius Cornelius Balbus (called Major) was born early in the 1st century B.C. Pompeius conferred Roman citizenship on him and his family for his services against Sertorius in Spain. Becoming friendly with all parties, he had much to do with the formation of the first triumvirate and was one of the chief financiers in Rome. He won the favour of Caesar and went with him as *praefectus fabrum* ("chief engineer") to Spain (61) and Gaul (58). His position as a naturalized foreigner, his influence and his wealth naturally made Balbus many enemies, who in 56 put up a native of Gades to prosecute him for illegally assuming the rights of a Roman citizen, a charge directed against the triumvirs equally with himself. Cicero, Pompeius and Crassus all spoke on his behalf, and he was acquitted.

During the civil war he tried to get Cicero to mediate between Caesar and Pompeius. Balbus became Caesar's private secretary and, after Caesar's murder, attached himself to Octavian; he was praetor in 43 or 42 and consul—an honour then first conferred on a provincial—in 40. The year of his death is not known. Balbus kept a diary of the chief events of his own and Caesar's life (Suetonius, *Caesar*, 81). The 8th book *De bello Gallico*, probably written by his friend Hirtius, was dedicated to him.

Lucius Cornelius Balbus (called Minor), nephew of the above, received the Roman citizenship at the same time as his uncle. During the civil war he served under Caesar. He also took part in the Alexandrian and Spanish wars. He was rewarded by being admitted into the college of pontiffs. In 43 B.C. he was (?pro-)quaestor in further Spain, where he made a fortune by plundering the inhabitants. In the same year he crossed over to Bogud, king of Mauretania. He is not heard of again until 21, when he was proconsul of Africa. On March 27, 19, Balbus, who had defeated the Garamantes, celebrated a triumph, which was then for the first time granted to one who was not a Roman citizen by birth, and for the last time to a senator. He built a theatre, which was dedicated at Rome in 13. Balbus wrote a play on his visit to Lentulus in the camp of Pompey at Dyrrhachium and, according to Macrobius, a work called *Exegetica*, on the gods and their worship.

BALCH, EMILY GREENE (1867–1961), U.S. economist and political scientist, received the Nobel prize for peace in 1946 jointly with John Mott (*q.v.*). She was born at Jamaica Plain, Mass., on Jan. 8, 1867, and educated at Bryn Mawr college, Bryn Mawr, Pa., from which she graduated in 1889. She later studied in Paris and Berlin. She taught at Wellesley college, Wellesley, Mass., from 1897 to 1918. She engaged in extensive public welfare activities, notably child welfare and the settlement movement and was a member of Massachusetts commissions on industrial relations (1908–09) and immigration (1913–14) and the city planning board of Boston (1914–17).

As a member of the Society of Friends (Quakers), she took an active part in the peace movement following World War I. She was a delegate to the International Congress of Women at The Hague (1915) and was secretary of the Women's International League for Peace and Freedom at Geneva, Switz. (1919–22), and later honorary international president. Aside from her writings on peace, her most important publication was *Our Slavic Fellow Citizens* (1910), the most sympathetic and thoroughgoing study of Slavic immigrants ever made, for which she traveled extensively in Europe and the U.S. to study Slavic backgrounds and the assimilation of Slavic peoples in the U.S. She died at Cambridge, Mass., on Jan. 9, 1961. (A. E. Wd.)

BALDACHIN, also called Ciborium, in architecture, the canopy over an altar or tomb, supported on columns, especially when free standing and disconnected from any enclosing wall. Early examples of the baldachin are found in the basilicas of Ravenna and Rome. The usual form consists of four columns supporting entablatures which carry miniature colonnades topped by a pyramidal or gabled roof. In Romanesque work arches generally replaced the entablatures, and gables frequently topped the four sides, as in S. Ambrogio in Milan. Few baldachins of the Gothic period remain, and their use, outside Italy, seems to have been spasmodic; there is, however, a rich Gothic example in the Ste. Chapelle at Paris (1247–50), reconstructed by E. E. Viollet-le-Duc in the 19th century, which shows great richness of carving, gilding, jeweling and the use of coloured enamels. In the Renaissance the use of the baldachin became commoner, probably as a result of the influence of the enormous bronze baldachin which Bernini designed for the altar of St. Peter's in Rome. These late Renaissance examples make frequent use of the spiral column supporting canopies of extremely fantastic design. *See* also Altar; Canopy. (T. F. H.)

BALDER (Baldr), in Scandinavian mythology, is the son of the chief god Odin and his wife Frigg. Balder is beautiful and just; most legends about him concern his death. Icelandic stories tell how he was slain by the mistletoe which the blind god Hödr, deceived by the evil Loki, hurled at him. Some scholars believe that the passive, suffering figure of Balder was influenced by that of Christ, but the Danish historian Saxo Grammaticus (*c.* 1200) depicts him very differently as a warrior engaged in a feud over the hand of a woman. (G. T.-P.)

BALDINUCCI, FILIPPO (*c.* 1624–1696), Italian art historian. Like Giorgio Vasari he was a Florentine partisan, but he was the first historian to make full use of documents. He was also the first to realize the importance of drawings in the study of painting; the great collection of drawings in the Uffizi palace in Florence is the result of his efforts. (P. J. My.)

BALDNESS (Alopecia) means the lack or loss of hair. Two primary groups of processes leading to baldness can be distinguished: (1) those causing permanent hair loss by destroying hair germ centres; and (2) those causing temporary hair loss by inflicting transitory damage on these centres.

The common patterned early male baldness occurring to some degree in more than 40% of men belongs in the first category. Heredity, age and male sex hormone are three factors recognized in the causation of this type of baldness. Dandruff, a frequently associated condition, seems to play no clearly causative role. No practical remedy for this common baldness is available. Other causes of permanent baldness include many scar-producing skin diseases and injuries, inborn lack of hair development and severe injury to hair germ centres by chemical or physical agents.

Temporary hair loss occurs fairly commonly after conditions accompanied by high fever. Loss of hair usually commences three months after the fever and generally regrows within a year. X-rays, metals and drugs (*e.g.*, thallium, tin and arsenic), malnutrition, some inflammatory skin diseases, chronic wasting diseases and endocrine disorders also can cause temporary excessive hair loss. Furthermore, alopecia areata, a fairly common disorder of unknown cause characterized by sharply outlined patches of sudden complete baldness, also usually causes only temporary injury to hair germ centres.

Finally, hair shaft disorders and fungous infections as well as mechanical factors such as rubbing can cause the appearance of baldness by breaking hairs off close to the skin surface. *See* also Hair. (A. L. Lz.)

BALDOVINETTI, ALESSO (Alessio) (1425?–1499), Florentine painter whose works typify Florentine academic painting of the later 15th century, appears to have been born in Florence on Oct. 14, 1425, and died there on Aug. 29, 1499. He is presumed to have been an assistant to Domenico Veneziano, whose influence is reflected in his earliest surviving works, three narrative scenes begun by Fra Angelico for the SS. Annunziata and an altarpiece painted about 1453 for the Medici villa of Cafaggiolo. It was followed, about 1457, by an altarpiece of the Annunciation for S. Giorgio sulla Costa, and by Baldovinetti's masterpiece, a fresco of the Nativity in the forecourt of the SS. Annunziata (1460–62), which has an important place in the history of Florentine landscape painting. To the same period belong

two panels in which a half-length Virgin is set in front of an extensive landscape, and the "Portrait of a Lady" (National gallery, London) sometimes ascribed to Paolo Uccello. Baldovinetti did two strips of mosaic decoration over Lorenzo Ghiberti's doors on the Baptistery in Florence (1453–55) and a St. John the Baptist over the south doorway of Pisa cathedral (1462). He also prepared designs for wood intarsias and for stained glass. As a painter he forms a link between Domenico Veneziano and Uccello on the one hand and Andrea del Verrocchio and Domenico Ghirlandajo on the other. Influenced by the Florentine naturalists, but himself devoid of a strong naturalistic bent, he was an artist of great sensibility, practising a static style.

See Ruth W. Kennedy, *Alesso Baldovinetti* (1938).

(J. W. P.-H.; X.)

BALDPATE, the common name for a North American duck (*Mareca americana*), allied to the European widgeon; also called "whistler" from the whistle of its wings in flight. *See* also Duck.

BALDRIC, a belt worn over one shoulder, diagonally across the body and under the other arm. It served either as an ornament or as a support for a sword, bugle, etc.

The shoulder belt (balteus) and the waist girdle (cingulum) supported the short sword of the Roman soldier. The baldric was a familiar object during the middle ages. Of the yeoman who attended the "parfit gentil knight" of the *Canterbury Tales*, Chaucer wrote, "A horn he bar, the bawdrik was of grene." To later generations it became a badge of rank. In the 17th century, the broad baldric that supported the rapier of the period was worn only by the nobility. It was richly embroidered and the ends were finished in a deep silk fringe. The baldric was partially covered by a handsome waist sash, below which the fringed ends were allowed to show. (E. L. Y.)

BALDUNG (Grün, Grien), **HANS** (*c.* 1484–1545), German painter, a contemporary of Dürer whose work is typical of the south German painting of the period, was probably born in Schwäbisch Gmünd in the winter of 1484–85. His youth was spent in Strasbourg, where he was the pupil of an imitator of Martin Schongauer. Between about 1503 and 1505 he was in Nürnberg as assistant to Dürer, who with Mathias Grünewald chiefly influenced his style. In 1509 he acquired "burgher's rights" of Strasbourg, but moved in 1512 to Freiburg im Breisgau, where he painted his masterpiece for the high altar of the cathedral and also a smaller altarpiece. In 1517 he returned to Strasbourg where he became official painter to the episcopate and also a member of the town council. He was an early supporter of the Reformation, and in a woodcut of 1521 represented Martin Luther protected by the Holy Ghost in the shape of a hovering dove. He died at Strasbourg in 1545.

Baldung was equally distinguished as draftsman and painter. A complete sketchbook of his is preserved in the printroom at Karlsruhe. He made numerous woodcuts, and glass paintings by him are in Freiburg cathedral, the church at Elzach and the museums of Basel, Karlsruhe, Cologne, Freiburg and Nürnberg. He also designed tapestries. His choice of subjects was varied. Besides religious pictures he painted portraits and fantastic allegories, particularly on the theme of "death and the maiden." His forms are full of energy and grace, his colours cool and delicate. In some of his representations of the Virgin Mary, landscape, figures, light and colour combine in an impression of magical serenity. His portrayals of age on the other hand have a sinister, demonic character and show a mannered virtuosity.

BALDWIN I (1172–1205), the first Latin emperor of Constantinople, was the son of Baldwin V, count of Hainaut, and Margaret of Alsace, countess of Flanders. He succeeded his mother (as Baldwin IX) in 1194 and his father (as Baldwin VI) in 1195. In the feudal politics of the age he joined with the Plantagenets and the Welfs and fought as an ally of Richard I of England against Philip II Augustus of France. In 1199 Pope Innocent III imposed a truce and ordered the preaching of a crusade. Baldwin took the cross and joined the other leaders of the expedition at Venice in 1202. He was present at the conquest of Constantinople in 1204 and, on May 9, was elected emperor of the new Latin state, being crowned on May 16. Boniface of Montferrat, the leader of the crusade, appeared to be a stronger candidate; but the Venetians, seeing in one so able and popular a possible rival to their own ambitions, supported Baldwin.

During his brief reign Baldwin faced a multitude of problems. His empire, which outside Constantinople had still to be conquered, was formally divided. The Venetians were allotted three-eighths of its capital and of its territories; one of their number became patriarch of Constantinople; and they were to be independent of Baldwin's authority. The other western magnates remaining in Byzantium became Baldwin's vassals for their lands there, the new state being based on feudal institutions; in Aug. 1204 he enfeoffed 600 knights. His authority over his great subjects was, however, insecure. Boniface of Montferrat claimed Thrace with Salonika, the second city of the empire, as his capital. Baldwin resisted these ambitions to the point of civil war, but was compelled, after baronial arbitration, to give way.

A revolt of the native population in Thrace provided the final crisis of the reign. The Greek rebels gained the assistance of the Bulgarian tsar Kaloyan. On March 25, 1205, Baldwin led a small force from his capital to besiege Adrianople, where he was joined by the Venetians under Enrico Dandolo. Kaloyan brought a large army to relieve the town, and on April 14 the Latins gave battle and were heavily defeated. Baldwin was taken prisoner and, despite Innocent III's intercession on his behalf, was murdered on the orders of Kaloyan.

In 1225 a pseudo-Baldwin appeared in Flanders and received much noble and popular support, being regarded as a saviour by the peasantry. In 1226, however, the imposture was exposed and the pretender executed.

Baudrillart, *Dictionnaire d'histoire et de géographie ecclésiastiques*, vol. vi (1932); R. L. Wolff, "Baldwin of Flanders and Hainaut, First Latin Emperors of Constantinople," *Speculum*, vol. xxvii, pp. 281–322 (1952).

BALDWIN II (1217–1273), Latin emperor of Constantinople from 1228, was a younger son of Yolande, sister of Baldwin I. Her husband, Peter of Courtenay, the third Latin emperor, had been followed by his second son Robert, upon whose death in 1228 the succession passed to Baldwin. The barons chose John of Brienne (titular king of Jerusalem) as emperor-regent for life: Baldwin was to rule the possessions of the empire in Asia when he reached the age of 20, to marry John's daughter Mary and, on John's death, to acquire the full imperial sovereignty. The marriage took place in 1234, but when John died (1237) the realm to which Baldwin succeeded was little more than the city of Constantinople. His lifelong task was to preserve his inheritance and to attempt its restoration to its former extent; but he was fatally hampered by crushing poverty.

In 1236 Baldwin had visited Rome, France and Flanders, trying to raise money and men, and in 1240 he was able to bring a considerable army back to Constantinople. But he could accomplish nothing with this help and traveled again in 1245 to Italy and then to France, where he spent two years. The empress Mary and Philip of Toucy governed during his absence. Louis IX of France bought some relics from him and redeemed his son Philip, whom Baldwin had had to give to some merchants as security for loans; but Baldwin spent most of his reign in inglorious mendicant tours.

In July 1261 Constantinople was captured by Michael VIII Palaeologus, ruler of the Greeks of Nicaea. Baldwin escaped in a Venetian galley to Negropont and then proceeded to Athens, whence he passed to Apulia and finally to France, still in quest of help from the western powers. He went to Italy in 1267 and, in May, induced Charles of Anjou to sign a treaty for the reconquest of Constantinople and to pension himself and his son Philip. In Oct. 1273 Philip married Beatrice, daughter of Charles, at Foggia. A few days later Baldwin died.

See works cited under BALDWIN I; also W. Norden, *Das Papsttum und Byzanz* (1903).

BALDWIN I (1058–1118), count of Edessa from 1098 to 1100 and king of Jerusalem from 1100 to 1118, was the son of Eustace II count of Boulogne and Ida of Lower Lorraine. Educated for the Church, he became canon of Reims, Cambrai and Liège, but in 1096 set off on the 1st crusade with his brother Godfrey of Bouillon. He and Godfrey parted company, however, in Asia Minor, when Baldwin answered the appeal of the Armenians of Cilicia for protection. There he came into conflict with the ambitions of Tancred (*q.v.*), and both he and Tancred gave up their original intentions. But Baldwin kept contact with the Armenians and established himself first at Turbessel (Tell-Bashir) in 1097, on the invitation of an independent Armenian community in the Euphrates valley and then at Edessa, on the invitation of the Armenian prince Thoros, who adopted him as his son. When Thoros was assassinated, Baldwin became the master of Edessa. He married the daughter of another Armenian leader and imposed his authority throughout the region (1098). Holding Edessa against a month's siege by the governor of Mosul, he enabled the other crusaders to take Antioch, but did not join their southward march, postponing his pilgrimage to Jerusalem till the end of 1099.

When Godfrey of Bouillon died, his knights invited Baldwin to take his place as "advocate of the Holy Sepulchre." Overcoming the intrigues of Tancred and the patriarch Daimbert, Baldwin compelled the latter to crown him king of Jerusalem (Dec. 25, 1100). He left his county of Edessa under his cousin Baldwin of Bourcq. As king he had to contend with Daimbert's claim to suzerainty over Jerusalem and Jaffa; in 1102 Baldwin succeeded in having Daimbert deposed by the papal legate, Maurice, thus consolidating the royal power in Jerusalem. Galilee was entrusted to him by Tancred, who had become regent of the principality of Antioch, and Baldwin successfully intervened in the affairs of other Latin states.

Baldwin conducted the war against the Muslims with vigour. He drove back a number of attacks from Egypt, imposed a truce on the prince of Damascus and repelled the counterattack by Mawdud, governor of Mosul. Taking advantage of the arrival of Italian, English and Norwegian fleets, he conquered the coastal towns (Arsuf, Caesarea, Acre, Beirut and Sidon). He also encouraged immigration of Christians from surrounding Muslim lands into his kingdom. Baldwin repudiated his Armenian wife and married, in 1113, Adelaide, the mother of Roger II of Sicily, but the patriarch compelled him to break with her in 1117. This cost him the friendship of the Norman kingdom of Sicily. He had no children by either marriage. He died on April 2, 1118, on the way back from an expedition against Egypt in which he had taken the town of Farama (Pelusium).

The kingdom of Jerusalem was Baldwin's creation. The royal power was made strong and the territory under Frankish rule had been considerably extended by the time of his death. He earned the title of "founder of the kingdom" assigned to him by his chaplain and biographer Fulcher de Chartres.

See P. Gindler, *Graf Baldwin I von Edessa* (1901); R. Grousset, *Histoire des croisades et du royaume franc de Jerusalem*, vol. i (1934); S. Runciman, *History of the Crusades*, vol. i and ii (1951–52).

(J. B. R.)

BALDWIN II (d. 1131), count of Edessa from 1100 to 1118 and king of Jerusalem from 1118 to 1131, was the son of Hugh, count of Rethel, and was first known as Baldwin of Bourcq (from Bourcq castle in the Ardennes; the usual form of the designation, Baldwin of Bourg, is wrong). Setting out on the first crusade with his cousin Godfrey of Bouillon, he accompanied him to Jerusalem but then retired to northern Syria, where, in 1100, Baldwin I, king of Jerusalem, handed over to him his county of Edessa. Captured by the Muslims in 1104 and held prisoner until 1108, he was only able to re-enter Edessa after a war with Tancred (*q.v.*), who had been appointed regent. The Muslim princes took advantage of this struggle until Baldwin I of Jerusalem mediated a reconciliation. In 1110 the governor of Mosul besieged Edessa and massacred the Armenians living to the east of the Euphrates, but Baldwin repelled further attacks from Mosul (1114–15) and was able to annex the last remaining independent Armenian principalities.

On the death of Baldwin I, in 1118, the barons of Jerusalem offered the throne to Baldwin, being persuaded by his cousin Joscelin of Courtenay to overlook the claims of Eustace III of Boulogne, brother of Baldwin I; Edessa was then transferred to Joscelin. Baldwin, however, had little opportunity to devote his energies to his new kingdom. The disaster of the "Field of Blood," in which the army of Roger of Antioch was destroyed, required Baldwin to undertake the defense of Antioch (1119), and he defeated the Muslims at Danith. When Joscelin was captured by the Muslims in 1122, Baldwin became regent of Edessa but he was himself captured in 1123. Released in 1124, he had to take part in the siege of Aleppo. He was not relieved of the regency of Antioch until 1126, when he married his daughter to the young prince Bohemund II. During his second captivity the regent of Jerusalem, Eustace Granier, with Venetian help, had conquered the port of Tyre (1124) and repelled an Egyptian attack. In 1129 Baldwin himself tried to seize Damascus.

The internal affairs of his kingdom were troubled by the patriarch Étienne of Chartres, who revived the claims of his predecessor Daimbert on the holy city; but on his death these were abandoned.

Baldwin initiated some important legislation: at the council of Nablus (1120) he achieved a series of decisions assuring the exercise of justice and determining the rights of the Church in the kingdom, with the recognition of the bishops' claim to tithes on the revenues of the king and nobles; and his later "Establishment" defined the degrees of treason and the liability of the barons to forfeit their lands for it.

Baldwin had no sons by his wife, an Armenian lord's daughter whom he had married before becoming king. His eldest daughter Melisande was married to Fulk V, count of Anjou, who succeeded him on his death (Aug. 31, 1131). Baldwin was the hero of a *chanson de geste* entitled *Baudouin de Sebourc*.

BIBLIOGRAPHY.—R. Grousset, *Histoire des croisades et du royaume franc de Jerusalem*, vol. i (1934); S. Runciman, *History of the Crusades*, vol. i and ii (1951–52); E. R. Labande, *Étude sur Baudouin de Sebourc* (1940); J. Richard, *Le Royaume latin de Jerusalem* (1953).

(J. B. R.)

BALDWIN III (1130–1163), king of Jerusalem from 1143 to 1163, was the eldest son of King Fulk (Fulk V of Anjou), whom he succeeded in Nov. 1143. His mother, Baldwin II's daughter Melisande, was at first crowned jointly with him (Dec. 25, 1143) and governed as regent with the support of the constable Manasses of Hierges, while Baldwin's brother Amalric inherited the county of Jaffa. At Easter 1150(?), Baldwin had himself crowned as sole ruler, but he had to divide the kingdom with Melisande. Shortly afterward, however, he entered into war with her. Having besieged Manasses in his castle Mirabel and taken him prisoner, he then besieged the queen in Jerusalem. Melisande finally yielded Jerusalem to the king and retained only Nablus as her dower (1151 or 1152).

The opening of the reign was marked by the advance of the Turkish ruler of Mosul, Zangi, and his son Nureddin in northern Syria. Edessa fell in 1144 and the second crusade was diverted from the reconquest of that county to an attack on Damascus, which Fulk had regarded as an ally against Zangi. Baldwin took part in the profitless siege of Damascus (1148) but finally renewed friendly relations with its prince. After Raymond of Poitou had been killed in battle against Nureddin, Baldwin had to go to the assistance of Antioch and decided to cede the remnants of Edessa, together with Turbessel (Tell-Bashir) and Marash, to the Byzantine empire (1150). In 1152 he had again to go to the assistance of Antioch and, on the death of Raymond II of Tripoli, to take over the regency of that county also.

Taking advantage of a lull on his northern frontier Baldwin put an end to Egyptian domination over Ascalon, which had long been a base for operations against the crusaders. Having already in 1150 built the castle of Gaza for the blockade of Ascalon, he captured the latter, after a siege, in 1153. He exacted a tribute from the Fatimid caliph in 1161 and had moreover laid the basis for the Egyptian campaigns of his successor.

Baldwin's efforts in the region of Damascus met with less success. Nureddin took Bozrah (Busra), which in 1151 the crusaders

had tried to recover for the prince of Damascus, and in 1154 he took Damascus itself. A truce was concluded between Nureddin and Baldwin, but Baldwin in 1156 treacherously attacked a nomad tribe protected by Nureddin. War began again, and Baldwin, coming to the help of the besieged Baniyas, was defeated at Jacob's Ford (1156). In 1157 he besieged Shaizar on the Orontes and then seized Harim (near Antioch). In 1158 he defeated Nureddin at Butaiha.

In 1158 Baldwin married the Byzantine princess Theodora Comnena. This enabled him to act as mediator between the Byzantine emperor Manuel I and the prince of Antioch, Raynald of Châtillon, when Manuel tried to subdue Cilicia and Antioch. He established friendly relations with the emperor, who imposed a peace treaty on Nureddin (1159). Baldwin was obliged to return to Antioch to settle the regency (1160) for Bohemund III, entrusting the government to the patriarch; he died in Feb. 1163, leaving no children.

Baldwin III was highly respected by his contemporaries, above all by the historian William of Tyre. Well educated, he had a love of history and was expert in customary law. "Courteous and eloquent," he imposed his authority on his barons without resorting to force and behaved with great generosity toward the church. He moreover avoided imposing oppressive taxes. He was anxious to give a good example to his subjects in his personal life, avoiding excesses in food and drink and conducting himself irreproachably as a husband; his courage in war was matched by his diplomatic skill. His qualities gained him the love of his subjects, the friendship of the emperor Manuel and the esteem of his enemy Nureddin. He failed, however, to prevent Nureddin from unifying Muslim Syria, lost Edessa and only with great difficulty maintained the integrity of other Latin states north of Jerusalem.

(J. B. R.)

BALDWIN IV (1161–1185), king of Jerusalem from 1174 to 1185, was the son of Amalric I by his first wife, Agnes of Courtenay. Educated by William of Tyre, he came to the throne in July 1174 at the age of 13. His succession created two problems; first, that of regency; the second, because he was a leper, that of succession. His kinsman Raymond III of Tripoli became regent, while the king's sister Sibyl was the lawful heiress. Sibyl in 1176 married William of Montferrat, to whom she bore a son (later Baldwin V), but William died in 1177, and in 1180 Sibyl married a young knight from the west, Guy of Lusignan. Henceforward the reign was troubled by dissensions of increasing bitterness between the court party (Sibyl and Guy, the queen mother Agnes, Agnes' brother Joscelin, and Raynald of Châtillon) and a baronial party led by Raymond of Tripoli. When Raynald of Châtillon took advantage of the position of his fortress of Krak, which lay on the great route of trade from Damascus and Egypt, to plunder the caravans (1182), he broke the truce of 1180 and thus precipitated an attack by Saladin (*q.v.*). In 1183 Guy of Lusignan was made regent by Baldwin IV, but, when Saladin launched a second attack, he declined battle and in November 1183 was deposed both from his regency and from his right of succession, Sibyl's son Baldwin being then proclaimed heir to the kingdom. For a time Baldwin IV resumed the government. Despite his disease, he showed all the great qualities of his predecessors, especially in military affairs; but early in 1185 he had to hand over the regency to Raymond of Tripoli, and in March 1185 he died.

BIBLIOGRAPHY.—The narrative of William of Tyre concludes with Baldwin IV's transfer of the regency to Raymond of Tripoli. *See* also S. Runciman, *History of the Crusades*, vol. ii (1952); M. W. Baldwin, *Raymond III of Tripolis and the Fall of Jerusalem* (1936).

BALDWIN V (1177–1186), nominal king of Jerusalem from 1185 to 1186, was the son of Baldwin IV's sister Sibyl by William of Montferrat (d. 1177). Proclaimed heir in March 1183, he came to the throne in March 1185 under the regency of Raymond of Tripoli. His reign was marked by the advance of Saladin and by dissensions between the government and Guy of Lusignan, Sibyl's second husband. Baldwin died in Sept. 1186.

BALDWIN, FRANK STEPHEN (1838–1925), U.S. inventor, best known for his creation of the Monroe calculating machine although his inventions ranged from railroad self-couplers to a metal lace latch for shoes, was born on April 10, 1838, in New Hartford, Conn.

Baldwin patented his first calculating machine in 1875, introducing a mechanical principle that enabled the device to add, subtract, multiply or divide in a direct and simple manner. In 1874 the machine was awarded the John Scott medal by the Franklin institute in Philadelphia as the most meritorious invention of the year. But it did not become a commercial success until after Baldwin became associated with Jay R. Monroe in 1911. From Baldwin's 1908 model the two men developed the Monroe calculator in 1912. The Monroe Calculating Machine company, organized that year, then became an important manufacturer of calculating machines. Baldwin was its research director until his death on April 8, 1925, at Denville, N.J. (M. Mo.)

BALDWIN, JAMES MARK (1861–1934), U.S. philosopher, was born at Columbia, S.C., Jan. 12, 1861, and educated at Princeton and several German universities. He was professor of philosophy in the University of Toronto (1889–93), of psychology at Princeton (1893–1903), of philosophy and psychology in the Johns Hopkins university (1903–09) and in the National University of Mexico until 1913. After lecturing at Oxford and the French provincial universities, he became professor at the École des Hautes Études Sociales, Paris, in 1919. Prominent among experimental psychologists, he received many honours from learned societies in America and Europe. His works include: *Handbook of Psychology* (1889–91); *Elements of Psychology* (1893); *Story of the Mind* (1898); *Mental Development in the Child and the Race* (1896); *History of Psychology* (1913); *Between Two Wars* (1926); and contributions to the *Dictionary of Philosophy and Psychology* (1901–05) and the *Psychological Review*, both of which he edited.

BALDWIN, MATTHIAS WILLIAM (1795–1866), U.S. locomotive manufacturer, was born in Elizabethtown, N.J., on Dec. 10, 1795, and was trained as a jeweler. Because of his skill with tools he was asked to build a locomotive, later named "Old Ironsides," for the Philadelphia and Germantown railroad in 1832. From this start came the Baldwin Locomotive Works.

Baldwin made a number of significant improvements in steam locomotives, notably a steam-tight metal joint that permitted his engines to use steam at 120 pounds pressure while others were limited to 60. His company built more than 1,500 locomotives during his lifetime.

He was also a philanthropist with a special interest in the welfare of the Negro. His abolitionist sympathies, in fact, led to the boycotting of Baldwin locomotives in the south. He died in Philadelphia, Pa., on Sept. 7, 1866.

(J. B. RA.)

BALDWIN, ROBERT (1804–1858), Canadian statesman, joint leader of "the great ministry" (1848–51) that established the principle of responsible, or cabinet, government in British North America, was born at York (Toronto), Upper Canada (Ontario) on May 12, 1804. He was called to the bar in 1825 and entered into partnership with his father, William Warren Baldwin (1775–1844), a prominent lawyer, physician and politician. In 1829–30 he sat in the parliament of Upper Canada for the town of York. In 1836 he was nominated to the executive council, but, with the entire council, resigned within a month. Though a Reformer, he strongly disapproved of the rebellion of 1837–38. On the union of Upper and Lower Canada he became (1841) a member of the executive council under Lord Sydenham, but soon resigned on the question of responsible government and, having been elected to represent Hastings in the assembly, went into opposition. In 1842 he formed under Sir Charles Bagot a largely Liberal administration with Louis (afterward Sir Louis) Lafontaine, which held office until nine of the ten ministers resigned in

1843, after a quarrel with Bagot's successor, Sir Charles Metcalfe. At the general election which followed, the governor general was sustained by a narrow majority, but in 1848 the Liberals were again returned to power, and he and Lafontaine formed their second administration under Lord Elgin which embodied the principle of responsible government and carried numerous important reforms, including the freeing from sectarian control of the University of Toronto and the introduction into Upper Canada of effective municipal self-government.

Internal dissensions soon began to appear in the Liberal party, and in 1851 Baldwin resigned after an attempt to abolish the court of chancery of Upper Canada, whose constitution was due to a measure introduced by Baldwin in 1849. The attempt, though defeated, was supported by a majority of the representatives from Upper Canada. On seeking re-election in York, he declined to give any pledge on the burning question of the Clergy Reserves (*q.v.*); he was defeated and retired to private life, devoting himself to bringing about better understanding between the English- and French-speaking inhabitants of Canada. In 1858 the Liberal-Conservative party, formed in 1854 by a coalition, attempted to bring him out as a candidate for the upper house, which was at that date elective, but though he had broken with the advanced reformers, he could not approve of the tactics of their opponents and refused to stand. He died at Toronto on Dec. 9, 1858.

(J. M. S. C.)

BALDWIN OF BEWDLEY, STANLEY BALDWIN, 1st Earl (1867–1947), British statesman, who was prime minister both during the general strike of 1926 and at the time of Edward VIII's abdication, owed his political success largely to the skill with which he presented himself to the public as a plain man, modest and unsophisticated. He was born at Bewdley on Aug. 3, 1867, the only son of Alfred Baldwin, chairman of the Great Western railway and head of the iron and steel manufactories and collieries known as Baldwins Ltd. After being educated at Harrow and at Trinity college, Cambridge, Baldwin went into his father's business; and when his father became member of parliament for Bewdley in 1892, Stanley Baldwin became virtually the head of the concern. For nearly 20 years the business was the central interest of his life. In 1906 he served his apprenticeship to politics by unsuccessfully contesting Kidderminster in the Conservative interest. Two years later his father died and Stanley Baldwin succeeded to the representation of the Bewdley division of Worcestershire. For nine years his record was that of a modest, unobtrusive back bencher.

Official Career.—In Dec. 1916, however, Andrew Bonar Law made him his parliamentary private secretary, and from that moment Baldwin's advancement was rapid. In Jan. 1917 he became a junior lord of the treasury, and in June joint financial secretary, in which capacity he gave valuable assistance in debate to Bonar Law and Austen Chamberlain, successively chancellors of the exchequer. In 1921 he became president of the board of trade. It was there that he first gave proof of his ability, but in party politics he was still almost an unknown factor.

His chance came in 1922. Support for Lloyd George's coalition government was by this time imposing too great a strain on the political allegiances of many Liberals and most Conservatives. Lloyd George and his personal followers were anxious to appeal again to the electors as a coalition. The majority of the Conservatives were opposed to them. The crisis came in Oct. 1922 when a meeting of the Conservative M.P.s was called at the Carlton club on Oct. 19. Austen Chamberlain presided, and his weight, with that of almost all his colleagues in the cabinet, was thrown into the scale of the coalition. A vigorous debate followed with momentous implications for the Conservative party's future.

The outcome was determined pre-eminently by two men, Bonar Law and Baldwin. Baldwin, with everything to lose politically by a false step, took his courage in both hands and made a speech characteristically brief and direct. He went at once to the "root of the whole difficulty—the position of the prime minister," and expressed his conviction that if the "present association" were continued, the disintegrating process in the Conservative ranks, already far advanced, would "go on inevitably until the old Conservative party was smashed to atoms and lost in ruins." Accordingly he declared himself "prepared to go into the wilderness" rather than continue the connection.

By 187 to 87 the meeting voted with Bonar Law and Baldwin. Austen Chamberlain and other Conservative leaders went into the wilderness (out of office)—temporarily—while, after a Conservative victory at the ensuing general election, Bonar Law became prime minister and Baldwin chancellor of the exchequer. A month later (Jan. 1923) Baldwin was sent to Washington, D.C., to negotiate a settlement of war debts. The terms he secured were less favourable than British opinion hoped for, and he was widely criticized for them. Nevertheless, when Bonar Law resigned his post as prime minister in May 1923, it was Baldwin, not the more experienced and distinguished Conservative, Lord Curzon, whom the king asked to form a government. For six months, in face of uneasy developments abroad, such as the Italian seizure of Corfu, and mounting unemployment at home, Baldwin's government pursued a tranquil course. Then, in October, Baldwin publicly announced his belief in protection as an economic cure and in November appealed to the country for a mandate to reverse Bonar Law's free-trade policy.

The mandate was refused. The Conservatives lost 107 seats and, though still the largest single party in the house of commons, were inferior to the Liberals and Labour combined. Baldwin resigned and Ramsay MacDonald formed a Labour government with Liberal support. At the end of nine months in office, however, MacDonald's government fell (Oct. 1924). The election that followed was bitter, with the Communist issue playing a larger role than the "safeguarding of industry" which Baldwin advocated. It was a resounding success for the Conservatives, giving them a majority of 211 over all other parties combined.

Baldwin formed a cabinet of Conservative reunion. He brought back Austen Chamberlain and Lord Birkenhead and, a year later, Arthur Balfour. Most surprisingly of all, he appointed Winston Churchill, still a free-trader, to the exchequer. When Churchill's first budget announced (along with a return to the gold standard) the restoration of the wartime McKenna duties and the silk tax, these were defended, not as tariffs, but as "revenue duties." These economic reforms did not, however, prevent a further slump in the coal trade and the threat of a stoppage of work over the owners' threat to reduce wages or lengthen hours. Baldwin initially refused to authorize a subsidy to the industry but subsequently agreed to one during the nine months while a royal commission was investigating the problem. The commission, however, failed to produce any alternative to a cut in wages. Rather than accept this, the miners went out on strike on May 4, 1926, and the Trades Union congress declared sympathetic strikes in such vital industries as transport, printing and engineering. Baldwin responded to the general strike by proclaiming a state of emergency, organizing volunteers to maintain all essential services and refusing all further negotiations with labour until the strike was called off. But although he was firm he avoided provocation, and the freedom from violence which marked the nine days' stoppage was in large measure a result of his wise policy. The collapse of the strike did not mean the end of the mines dispute. In June 1926, in face of bitter opposition, the government carried a bill which permitted a return to the eight-hour day, but it was November before the miners succumbed. Finally, in 1927 Baldwin sponsored the Trades Disputes act designed to curb the power of the unions in various ways.

Foreign affairs were of less interest to Baldwin, and the substitution of the Locarno agreements for the Geneva protocol, mainly the work of Austen Chamberlain, constituted the principal diplomatic achievement of these years. At home, Baldwin's administration continued without any notable event until 1929. Then, on the slogan of "Safety First," he appealed to the electorate. Hostility to the Trades Disputes act and concern over mounting unemployment impelled the Labour party to victory and put Baldwin back on the opposition front bench.

In 1931 Baldwin's chance came again. The collapse of the Labour government in the financial crisis led the king to invite MacDonald to form the National government, in which Baldwin

accepted the lord presidency of the council. Under the National banner an overwhelmingly Conservative house of commons was returned, in which Baldwin, though ostensibly subordinate to MacDonald, was in fact the dominant figure. It was his influence that determined Conservative endorsement of the Indian Round-Table conferences (at the price of the withdrawal of Churchill's support), and he was the moving spirit behind the 10% ad valorem tariff and the Ottawa agreements of 1932 which established protectionism and, by forcing Liberal resignations, largely destroyed the national character of the government. In these years there began the progressive decline in British support for collective security and national defense which were the keynote of the 1930s, and while Baldwin cannot be held directly and positively to blame for the misfortunes, national and international, which ensued, his sins of omission explain many of the disasters which marked the end of the decade.

In June 1935 MacDonald resigned from public life and Baldwin succeeded to the title as well as to the realities of power. In October he fought an election on a program of support for the League of Nations and businesslike reform at home. He retained the National government's large (and overwhelmingly Conservative) majority and formed a cabinet principally notable for the appointment of Anthony Eden as minister for League of Nations affairs. Within a month, however, the administration was involved in the discredit of the Hoare-Laval deal (*see* English History), from which only the resignation of Sir Samuel Hoare extricated them. In 1936 there occurred the German reoccupation of the Rhineland, the completion of the Italian conquest of Ethiopia and the beginning of German-Italian intervention in the Spanish Civil War. All these events left Baldwin seemingly unruffled, but the crisis simultaneously developing at home over the attachment of the new king, Edward VIII, to Mrs. Wallis Simpson presented him with a challenge better suited to his powers. Intuitively responsive to public feeling, both in Great Britain and the empire, over such an issue, Baldwin made it his aim to settle it so as to preserve imperial unity and the prestige of the monarchy unimpaired. A unique responsibility rested on him as virtually sole intermediary on this issue between the king and his people, a responsibility which he discharged with delicacy and resolution. To Baldwin, more than to any other man, goes the credit for avoiding a disastrous breakdown in the functioning of the constitution.

On May 28, 1937, Baldwin resigned the premiership to Neville Chamberlain and, on his retirement from the house of commons, accepted elevation to the peerage. He played virtually no part in politics after this and died in retirement on Dec. 14, 1947.

Personality and Character.—The career thus outlined is one of the most remarkable in English political history. Fortune was undoubtedly kind to Baldwin, but he was also a man of remarkable qualities. His public spirit was well illustrated by his action in June 1919 in anonymously presenting to the exchequer for cancellation £150,000 of the new war loan, a sum representing approximately 20% of his total fortune. He hoped, in this way, to set an example of personal sacrifice.

There was also in his make-up a latent puritanism. He combined indifference to the trappings of power with a remarkable adroitness in its exercise. With the years his intellectual laziness and administrative laxity increased, but his modesty and apparent simplicity won him to the end of his political career an easy indulgence for faults not usually found pardonable in the holders of great offices. He scorned all the obvious devices of publicity yet projected his personality with extraordinary success at a time when the public craved, above all else, an assurance of security, normality and peaceableness. He had a deep love for the English countryside and a literary capacity above the ordinary; when the two were combined as in his volume of nonpolitical addresses *On England* (1926) the result could be singularly attractive.

Bibliography.—Baldwin's printed speeches include the following collections: *Employment, Trade, and Empire Development* (1923); *Peace and Goodwill in Industry* (1925); *Our Inheritance* (1928); *This Torch of Freedom* (1935); *Service of Our Lives: Last Speeches as Prime Minister* (1938); *An Interpreter of England: The Falconer Lectures* (1939). *See* also G. M. Young, *Stanley Baldwin* (1952); A. W. Baldwin, *My Father: the True Story* (1956).

(J. A. R. M.; H. G. N.)

BALE, JOHN (1495–1563), English bishop, dramatist and Protestant controversialist, notable for his antiquarian researches and his part in the religious strife of the 16th century, was born at Cove, near Dunwich, Suffolk, on Nov. 21, 1495. He was educated at the Carmelite convent in Norwich, and Jesus college, Cambridge, where he took his B.D. in 1529. He was prior of Carmelite convents at Maldon, Doncaster and Ipswich at various times, but became a Protestant, and at some date (probably 1533) left his order, married and obtained the living of Thorndon, Suffolk. Frequently attacked and once imprisoned for his religious views, he took refuge on the continent in 1540 upon the fall of his protector, Thomas Cromwell. In 1548 he returned to England, and was made rector of Bishopstoke, Hampshire (1551), and bishop of Ossory, in Ireland (1552). On the death of Edward VI in 1553 he fled abroad once more, returning after the accession of Elizabeth. In 1560 he received a prebendal stall at Canterbury, where he died in Nov. 1563.

Bale's voluminous writings are characterized by a fiercely partisan spirit, crude but vigorous satire and frequent scurrility. His plays, only five of which survive, published as *The Dramatic Writings of John Bale*, ed. by J. S. Farmer (1907), are thought to belong, in their first version at least, to the early 1530s. They employ the old forms of miracle and morality play as vehicles of Protestant propaganda. The most vehement in its attack on the Roman church is *A Comedy concernynge the 3 Lawes of Nature, Moises and Christe, Corrupted by the Sodomytes, Pharyses and Papistes Most Wicked* (1562). *Kynge Johan*, which identifies the personified abstractions of the morality play with real persons such as Pandulph and Stephen Langton, is often claimed as the first English history play.

Bale wrote many other polemical works, chief among which are the *Brefe Chronycle concernynge Syr Johan Oldecastell* (1544), *The Actes of Englysh Votaryes* (1546), the *First Examinacyon* (1546) and *Lattre Examinacyon* (1547) of Anne Askewe, and *The Image of Bothe Churches* (1548). But it was his search for "Englandes Antiquitees" which won Bale the esteem of scholars, both English and continental, and his passion for collecting and listing old books that produced his most monumental work, three biographical catalogues of English writers: the *Illustrium Majoris Britanniae Scriptorum, hoc est, Angliae, Cambriae, ac Scotiae, Summarium* (1548); the revised and much expanded *Scriptorum Illustrium Majoris Britanniae . . . Catalogus* (1557–59); and the autograph notebook, first published in 1902 by R. L. Poole and M. Bateson as *Index Britanniae Scriptorum quos . . . collegit Joannes Baleus*. Though marred by inaccuracy and Protestant bias, these volumes are invaluable to students of the medieval and early Tudor period, and form the first, rudimentary history of English literature.

BALEARIC ISLANDS (Islas Baleares), an archipelago of five islands, with a number of islets, in the western Mediterranean, lie 50 to 190 mi. off the east coast of Spain, of which they form a province. Pop. (1960) 443,327. Area 1,936 sq.mi. The archipelago, which lies between 38° 40′ and 40° 6′ N., and 1° 22′ and 4° 25′ E., comprises two distinct groups. The eastern and larger group, the Balearics proper, contains the two principal islands, Majorca (Spanish, Mallorca) and Minorca (Menorca), and the small island of Cabrera, south of Majorca. The western group, formerly known as the Pine Islands (Las Pitiusas; ancient Pityusae), comprises Ibiza (Iviza) and Formentera, with several islets. Majorca, Minorca and Ibiza are described in separate articles, and Formentera with the last named.

Physical Geography.—The Balearic Islands are, structurally, the continuation of the Andalusian mountains which end on the Spanish mainland at Cabo de la Náo, a little more than 50 mi. west of the Pityusae. They are the emergent portions of two submarine

plateaus which are separated from each other by a considerable marine depression. The seas separating Ibiza from Formentera and Majorca from Minorca are, however, relatively shallow, and a fall of the Mediterranean sea level of 300 ft. would convert the Balearics into two islands. The edge of the northern submarine plateau is truncated abruptly by an east-west abyss more than 8,000 ft. deep. Minorca's northwest-southeast axis lies obliquely to the direction of this fault zone; and the character and extent of the Palaeozoic formations of Devonian Age comprising the island suggest that Minorca is a remnant of the continental massif which formerly united Sardinia with Catalonia. The other islands of the Balearics are aligned on the southwest-northeast trend of the submarine plateaus, and presumably are the expression of violent Alpine folding from the southeast. Rocks from Trias to Oligocene bear witness to these mountain-building movements, older formations being brought up also as inliers.

The resultant sierra of northwest Majorca, parallel to the coast, rises in the Torrellas or Puig Mayor to 4,734 ft.; a minor highland zone in the southeast reaches almost 2,000 ft.; and the core of Ibiza is crowned by La Atalaya, 1,558 ft. The rugged and precipitous cliff coastlines of both northwest Ibiza and northwest Majorca, often referred to as their Costa Brava, occur where these zones of high relief are adjacent to the sea. Elsewhere in Majorca and Ibiza there are broad belts of lowland, often of fertile Miocene soils or alluvium, surrounded or interrupted by undulating hills, boulder-strewn and scarred by the courses of torrents which in flood spread their debris on the piedmont zone. Formentera has a more monotonous relief, consisting of two tablelands (the higher, La Mola, 630 ft.) mainly of Quaternary deposits connected by a narrow isthmus of alluvium. Minorca has a more worn terrain, the highest of its small hills, Monte Toro, in the north centre, reaching an elevation of only 1,174 ft. This northern monotonous stony plateau runs to the sea in a northeast coast of much more dislocated relief which contains many bays and capes and the deep inlet of Mahón. A fairly well-marked depression separates this plateau from the low southern tableland with its gently rolling surface cut by broad ravines with fertile alluvial bottoms. Cabrera, separated by a 5-mi. wide strait from Majorca, is a semi-arid continuation of the larger island's eastern hills.

Within a general pattern of Mediterranean climate characterized by winter rain and summer drought, there are marked variations from one island to another, and within each island, dependent largely on relief and aspect. Minorca, having no protecting range of mountains, is colder and wetter in winter (25 in. annually), and feels the effects of hot summer winds more than the other islands. The average summer temperature is 75° F., and that of winter 50° F. In Majorca there are marked differences between the rainy cooler northern mountains and the protected remainder of the island, which has an average rainfall of less than 20 in. and rarely suffers gales. Ibiza, Cabrera and Formentera are even drier, with an annual precipitation of less than 15 in. In all the islands the period May–August is almost rainless, the number of rainy days being less than 80 annually. There are, therefore, no permanent streams but a great number of torrent courses and ravined gullies which are filled spasmodically. Snow rarely falls, although frosts are not uncommon in the period January–March. In the mountains of Majorca snow may lie for several weeks until the spring thaw. Daytime summer temperatures frequently reach the 90s in June, July and August, but these are moderated by sea breezes, and the evenings are usually cool and often in the 50s even in mid-summer.

Agricultural and pastoral use of the lowland areas, and the construction of hillside terraces for arable farming have limited natural vegetation to the rocky hilly lands, ravines and terrain impracticable for farming. The exposed northern areas of Minorca are either treeless or support only stunted specimens, but the sheltered southern gullies (barrancas) have some pine woods, pomegranate orchards and even semitropical vegetation on their slopes. In the other islands Aleppo and Stone pine and some holm oak occur where rainfall and soils are sufficient, but great areas are covered with Mediterranean scrub vegetation, which includes juniper, oleander, myrtle and rock roses. This *garigue* was formerly the undergrowth of a forest cover. The prevailing arboriculture of Majorca and Ibiza has resulted in a two-tier cover of the fertile parts of those islands (*huertas*), as cereals and legumes are grown in the orchards and groves of almond, olive, carob bean and fig trees. Artificial meadows of lucerne occur in the most easily irrigated areas. (G. J. B.)

Archaeology.—The earliest historical records describe the inhabitants of the Balearic Islands as cave dwellers. Natural and partly artificial caves abound in the limestone rock and have produced the few simple flint implements and incised pottery which can be assigned to the beginning of the Bronze Age and are the earliest records of human activity. Subterranean methods of living persisted, and the walled settlements of the inhabitants largely consisted of windowless rooms. Megalithic hill forts crown some of the hills.

Talayots.—The earliest and best known monuments are the talayots (towers). They are still numerous and were formerly much more so, especially in the intensively cultivated island of Majorca, where great numbers were destroyed, particularly on the plains adjoining the southeast coast of the island. They are chambered towers of stone, with either a round or a rectangular plan. They were roofed, generally with the aid of a central pillar composed of circular superimposed slabs, and faced with clay to produce a monolithic appearance.

The masonry of the round towers is very rough, the walls being composed of immense rugged blocks of hammer-dressed limestone; but the four-cornered talayots, which are presumably later, show smaller masonry. As a class the talayots are obviously akin to the nuraghi of Sardinia, and, like the nuraghi, they served as fortified dwelling places; outbuildings are normally attached and they are occasionally sited within villages enclosed by cyclopean walls, which also sometimes contain structures reminiscent in plan of those of Malta.

Taulas.—With the talayots in Minorca are associated the so-called "temples"; these halls may well have been used for ceremonial purposes, but they certainly formed a normal element of the habitations associated with the talayots. They are enclosures, usually of D-shaped plan, with the entrance in the straight side; within the area stands a taula (table), a rectangular slab of dressed stone, up to as much as 15 to 16 ft. in height, supporting a second, horizontal, slab, also carefully dressed and in one case measuring about 12 ft. 6 in. by 5 ft. 6 in. and about 2 ft. thick. These T-shaped taulas are central supports for roofing, an explanation warranted by the facts that there are often supplementary pillars between the taula and the outer wall and clay covered pilasters against the wall and in the angles, and also that the taula method of roofing is actually employed in the artificial grottoes. These halls and the adjoining rooms appear to have been built without windows.

It seems certain that these most remarkable prehistoric remains in Majorca and Minorca are not likely to be much earlier than the middle of the second millennium B.C. and represent a culture that continued with little change until Roman times.

Burial Caves.—Rock cut tombs and burial caves are found in many forms; those of the best known series, at San Vicente, on the northern extremity of Majorca, are cut into a sloping hillside. Outside the narrow doorway of the principal tomb is a forecourt, 20 ft. by 17 ft.; and within it a short antechamber from which a second doorway leads into the main chamber, 30 ft. long by 6 ft. wide; an overall length of over 60 ft. There are also small side chambers. This general type compares closely with the burial grottoes of southern France near Arles and must indicate a common origin. Carvings in Majorcan caves confirm the relationship. Many caves of the same type, when sited on level ground, are approached by steps sunk in a trench which was filled by blocking material to seal the tomb. There are many varieties of these artificial grottoes.

The *naus* or *navetas* (Catalan, "ships"), so termed from their resemblance to an upturned boat, were also graves. These are now found chiefly in Minorca, and are elongated structures built, like the talayots, of immense closely fitted blocks of stone, with a rounded end and squared or slightly concave front; in this front

face is a tiny door giving access from a forecourt through a passage to a long rectangular chamber roofed by large slabs. In the famous Nau d'Es Tudons the total length of the structure was about 60 ft., the width 24 ft. and the height about 25 ft. It is likely that the entrance to the artificial cave so formed was sealed by a structure built on the D-shaped forecourt, to match the rounded end and present a symmetrical and impenetrable artificial mound. The monument was, in fact, the equivalent of the long barrow of the west (*see* BARROW), while the plan of the passage and chamber within the *naveta* is almost the same as that of the larger burial caves, and the early date of each is indicated by the discovery in them of V-bored buttons. Structures of somewhat similar form in Majorca seem to have been used as dwellings.

Carthaginian Influence.—Ibiza was a Carthaginian stronghold and there is little evidence of any other civilization on that island. Minorca also was occupied by the Carthaginians, as the name of its principal harbour, Mahón (Portus Magonis), still bears witness; and Jama (now Ciudadela) was a Carthaginian town; but there the native civilization of the island as a whole persisted.

Roman Influence.—The islands were conquered by Q. Caecilius Metellus in 123 B.C., and thereafter remained part of the empire and supplied contingents of slingers to the Roman armies. Palma and Pollentia (now the site of the medieval town of Alcudia) were the principal cities.

Finds.—Although the Talayotic civilization seems to have continued without much modification, the position of the islands off the northern shore of the Mediterranean laid them open to continued influence from more eastern civilizations, as many finds attest. Important discoveries of bronze swords and single and double axes, antennae swords, heads and figures of bulls and other animals—doves crowning sceptres, small human figures from Sardinia or farther east, and many other objects, all bear witness to the foreign trade of the islanders over long periods of time. Local manufactures are represented by quantities of pots and shards, mostly of the native talayotic types; *i.e.*, fragments of spherical pots, often furnished with a number of small loops for suspension, and other forms, as well as the biconical cups with a hollow foot which are peculiar to the talayotic civilization. Most of the types seem to have persisted with little change until they are found mixed with Roman wares following the Roman occupation, during which period the ancient structures were extensively occupied and quantities of Roman pottery, etc., were produced. Small objects of cast lead, presumably votive, are also of native origin.

Such finds may be studied in the museums at Artá, Manacor, Alcudia, Mahón in the islands, as well as at Barcelona and Madrid, Spain; and Minorcan pottery and art in the Museum of Ethnology at Cambridge, Eng. (W. J. HE.)

History.—There is historical evidence of at least 2,600 years of settlement, for the islands passed successively under the rule of Carthaginians, Romans, Vandals, Moors and Spanish, all of whom have left their mark to some extent on the physical and cultural landscape. The islands are thus in many ways an epitome of Mediterranean insular history. Ibiza in particular was a strategic point of great importance, easily reached via the north African coast and providing a convenient base to raid the rich lands of Alicante, Valencia and Majorca. Known to the Greeks, and occupied for centuries by the Phoenicians and Carthaginians, Ibiza became a Roman colony in 123 B.C. Under all these occupations its economic resources of lead, zinc, salt, foodstuffs and purple dye (from marine molluscs) were sought by traders. Similarly Majorca and Minorca became important links in Punic War strategy, Mago, Hannibal's brother, wintering at Mahón in 206 B.C. When the archipelago was conquered by Q. Caecilius Metellus, the largest city of the Balearics, Palma (*q.v.;* the symbol of victory), was founded and olive cultivation was introduced. A five centuries' peace, during which the islands supplied their new masters with Minorcan mules and the celebrated Balearic slingers, was broken by the arrival of the Vandals, who were followed by the troops of the Byzantine emperor, Justinian. Though raided frequently both by Muslims and by Normans, the islands were not permanently conquered by the Caliphate of Cordoba until 903. The Moorish occupation led to many improvements in agriculture and irrigation, notably the introduction of windmills and water wheels turned by animals, both devices being conspicuous features of the landscape today. Majorca and Minorca became the objective of a great Pisan-Catalan crusade which in 1116 temporarily succeeded in liberating thousands of Christian slaves and in destroying the Moors' piratical bases. Although the Muslims rapidly re-established their hold, James I of Aragon (the Conqueror) annexed Majorca and Ibiza in 1230–35, Minorca falling to his descendant Alfonso III in 1286. The islands formed a semi-autonomous kingdom until 1349 and became a great base of medieval cartography and navigational science. Settlement was extended, agriculture was developed and trade prospered. In 1521 a peasant rebellion wiped out many of the nobility of Majorca, the insurrection being suppressed only with difficulty. In 1535 Barbarossa plundered Mahón, and other Barbary pirates continued their raids throughout the 16th century. In the War of the Spanish Succession the strategic value of the large landlocked harbour of Mahón attracted the attention of the participants, and its capture by the British in 1708 ushered in a century of dispute over its possession, which was not finally settled until the Spanish regained it in 1802 by the peace of Amiens. (*See* also MAHON.) In the Spanish Civil War (1936–38) points in the islands were seized by insurgent troops. Loyalist forces temporarily recaptured Ibiza, Formentera and Minorca, the latter serving as an important base for their naval operations. For a time it was expected that the islands would be ceded to Italy in return for aid extended to Gen. Francisco Franco during the hostilities.

Population.—More than 80% of the population of the Balearics live in Majorca, one-third of all the islanders residing in Palma alone. Most of the Majorcans and Minorcans are town-dwellers, but the reverse is true of Ibiza and Formentera where two-thirds of the people live in rural settlements. Cabrera and Formentera are thinly populated, the former having only 38 inhabitants. Majorca has a population density of 258 per sq.mi., Minorca, 158, and Ibiza, 6 per sq.mi. Ethnically the people reflect the rich variety of their historical antecedents. The larger towns contain a majority of folk of Catalan descent, with Jewish and Italian minorities, but the country districts show in their physical types important admixtures of Moorish, Phoenician, Greek and even Nordic characteristics, and some families can trace their ancestry to Moorish-Catalan progenitors. There are also small numbers of returned emigrants, from the mainland, from France and from Latin America, the latter known as *americanos.* Castilian is the language of the cities, but in rural areas a Catalan dialect, with many resemblances to Provençal French and with several Arabic infusions, is the common tongue spoken. Some Majorcans returned from France and residing in Sóller speak French; and some forms of speech introduced by the British still survive in Minorca.

Administration and Economy.—All the islands together form a Spanish province, with Palma as its capital. The city is also the military, judicial and ecclesiastical headquarters of the province. Minorca and Ibiza (with Formentera) are separate dioceses and judicial districts, the *audiencia* of Majorca being divided into three subdistricts. Local administration is carried on through communes, Majorca having 52, Minorca 7 and Ibiza 6 such divisions.

Arboriculture is the traditional industry of Majorca and Ibiza, cereals, legumes and animal fodder crops being grown among the almond, carob bean, fig, olive and apricot trees, either on the irrigated *huerta* lowlands or on the intensively terraced hillsides. Minorca is more important for pastoralism but also produces good crops of oranges. Stock-raising is widespread in all the islands, small groups of sheep, goats and pigs being cared for by the women and children. *Feixes* or reclaimed lands, adjacent to Ibiza city, are important sources of market-garden produce. This rural economy is essentially peasant-operated, much of the domestic furniture, foodstuffs, local customs and arts exhibiting distinct self-sufficient characteristics. Almonds, figs and apricots are exported, and there is a considerable local production of wines, olive oil, butter, cheese and poultry.

For centuries Ibiza has been an important manufacturer of sea salt, about 70,000 tons annually being sold to Britain, Scandinavia and Iceland for fish-salting. Fishing provides much food for the islanders, and some is exported to the mainland. Timber-cutting, charcoal-burning and small glass, pottery, footwear and foodstuffs factories complete the industrial fabric, but many of these occupations are complementary and secondary to agriculture, having a labour supply which fluctuates with the demands of the farmland.

The tourist industry is an important part of the economy of all the islands, many thousands of visitors, especially from Spain, France, Great Britain and Germany, being attracted by the climatic, scenic and historic merits of the Balearics. The construction of hotels, guest-houses and villas, the provision of services, and the making and sale of souvenirs, especially fine lace and embroidery, provide employment and income.

Sea communications are maintained principally through Barcelona, and air services link Majorca and Minorca with many west European cities. (G. J. B.)

BALEN, HENDRICK VAN (1575–1632), Flemish painter, chiefly of religious subjects, was born in Antwerp in 1575 and died there on July 17, 1632. He was a pupil of Adam van Noort. After traveling for a time in Italy, he joined the Guild of St. Lucas at Antwerp in 1593. Balen was the first master of Van Dyke; he collaborated with various painters, including Jan Brueghel and Frans Snyders.

Balen's painting of the Holy Family is in the chapel of Notre Dame, Antwerp. Other pictures at Antwerp are "The Trinity" and "The Adoration of the Kings"; the Musée de Paris has two, "The Holy Family in the Desert, Attended by Angels" and "Abraham Sending Away Agar and Her Son Ismael."

BALES (Balesius), **PETER** (1547–1610?), English calligraphist, one of the inventors of shorthand writing, was born in London in 1547, and is described by Anthony à Wood as a "most dexterous person in his profession. . . ." John Evelyn speaks of him as having written, in the year 1575, "the Lord's Prayer, the Creed, Decalogue, with two short prayers in Latin, his own name, motto, day of the month, year of the Lord, and reign of the queen, to whom he presented it at Hampton Court, all of it written within the circle of a single penny, inchased in a ring and borders of gold, and covered with a crystal, so accurately wrought as to be very plainly legible; to the great admiration of her majesty, the whole privy council, and several ambassadors then at court." Bales was very dexterous in imitating handwritings, and between 1576 and 1590 was employed by Walsingham in certain political maneuvers. He was the head of a school near the Old Bailey, London, in 1590, when he published his *Writing Schoolemaster, in three Parts*. This book included an *Arte of Brachygraphie*, which is one of the earliest attempts to construct a system of shorthand. He died about the year 1610.

BALFE, MICHAEL WILLIAM (1808–1870), Irish singer and composer, best known for his opera *The Bohemian Girl*, was born in Dublin, May 15, 1808. He appeared as a violinist at the age of 9 and began composing at about the same time. In 1823 he went to London, where he played in the orchestra at Drury Lane theatre, and in 1825 was taken to Rome by Count Mazzara, a wealthy patron. He had lessons with Ferdinando Paer, and later in Milan. Between 1827 and 1833 he sang leading baritone roles in operas by Rossini, Meyerbeer and others in Paris and Italy. His own early operas were written on Italian librettos and produced at Palermo, Pavia and Milan between 1829 and 1833, when he returned to London. His first English opera, *The Siege of Rochelle*, was produced at Drury Lane in 1835. His popularity was established; in 1838 he sang Papageno in the first English performance of *The Magic Flute*, and with *Le Puits d'amour* (Paris, 1843) he began a series of French operas.

The Bohemian Girl (Drury Lane, 1843) was the most successful of all his operas and was produced in many countries, in French, German, Italian and Russian. The most popular English opera of the first half of the 19th century, it was distinguished by its melodies which, though criticized as conventional and sentimental, are spontaneous and singable. Two of the ballads from it, "When Other Lips" and "I Dreamt that I Dwelt in Marble Halls" have been published in many arrangements.

Balfe also produced several other operas in London, essayed management and conducting, but with little success, and between 1849 and 1864 traveled in France, Germany, Italy and Russia. He retired to Rowney abbey, near Ware, Hertfordshire, where he died, Oct. 20, 1870.
